▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

WHY STUDY EXCITED STATES?

Where are the 'missing' resonances? (N^*)

- Compare experiment (PDG '09) to quark model (Capstick, Roberts '00)
- Too many d.o.f in the QM? Reduced by diquarks (Jaffe)
- ► Experiment is mostly → Nπ. States which couple weakly? N* program at JLab.

Where are the 'QCD Exotica'?

- Hybrids?: Charmonia, GLuEX, BESIII
- Tetraquarks?

Spectroscopy in Lattice QCD

▶ Finite a, L, and T. Calculate Euclidean n-point functions

Spectral rep. of two point functions:

$$\begin{split} C^{2pt}(t) &= \langle 0 | \mathcal{O}(t) \bar{\mathcal{O}}(0) | 0 \rangle = \sum_{n} A_{n} \mathrm{e}^{-E_{n}t} + \mathrm{O}(\mathrm{e}^{-ET}), \\ A_{n} &= |\langle 0 | \hat{\mathcal{O}} | n \rangle|^{2} \end{split}$$

What are 'Resonances'?

- Def: Poles in the S-matrix on 2nd Riemannian sheet
- Often show up as 'bumps' in the cross section

Maiani-Testa No Go Theorem: S-matrix elements cannot be obtained from (I.V.) Euclidean correlators (except in principle at threshold).

Källén-Lehmann representation:

$$\Delta(p) = \int_0^\infty d\mu^2 \ \rho(\mu^2) \frac{1}{p^2 - \mu^2 + i\epsilon}$$

In I.V., $\rho(\mu^2)$ has δ -functions, and a continuum above threshold.

In F.V. $\rho(\mu^2)$ is discrete above threshold.

Behavior of F.V. energies below inelastic thresholds is well known (Lüscher '86). Generalizations:

- Moving frames: Gottlieb, Rummukainen '95
- ▶ Multiple 2-particle channels: Liu, Feng, He '05
- ► ...
- 2 Non-identical particles, moving frame: Leskovec, Prelovsek '12

General prescription to extract I.V. resonance info above 3 (or more) particle thresholds lacking.

Below threshold, F.V energy corresponds to I.V. bound state up to $\mathcal{O}(e^{-m_{\pi}L})$.

Near threshold, F.V energies are distorted. Avoided level crossing occurs.

Example: taken from (Gottlieb, Rummukainen '95)

- Two scalars: $4m_{\phi} > m_{\rho} > 2m_{\phi}$, $\mathcal{L}_{int} = \frac{\lambda_1}{4!}\rho^4 + \frac{\lambda_2}{4!}\phi^4 + \frac{g}{2}\rho\phi^2$
- Spectrum from GEVP with single and multi-particle ops.

• Left:
$$g = 0$$
, Right: $g = 0.008$

◆□ → ◆□ → ◆三 → ◆三 → ● ● ● ●

THE GEVP

Solve (Lüscher, Wolff '90)

$$egin{aligned} \mathcal{C}(t) \mathbf{v}_n(t,t_0) &= \lambda_n(t,t_0) \mathcal{C}(t_0) \mathbf{v}_n(t,t_0), \ \mathcal{C}_{ij}(t) &= \langle \mathcal{O}_i(t) ar{\mathcal{O}}_j(0)
angle \end{aligned}$$

Method 1:

- Avoids diagonalization at large t
- Solve GEVP for $t = t_*$. Discard $\lambda_n(t_*, t_0)$.
- Use $\{v_n(t_*, t_0)\}$ to rotate C(t).
- Ensure that the off-diagonal elements remain small.

Method 2:

- Diagonalize on each t
- ▶ (Blossier, et al. '10): If *t*₀ > *t*/2

$$E_n^{eff}(t,t_0) = -\partial_t \log \lambda_n(t,t_0) = E_n + \mathcal{O}(e^{-(E_{N+1}-E_n)t})$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

In practice, weakly coupled low-lying states are problematic

Reduce ψ_{i1} , i = 1..3 by 100:

◆□ > ◆□ > ◆豆 > ◆豆 > ̄豆 = のへで

SIMPLE OPS AREN'T ENOUGH

Using the GEVP, can access the $\psi_{im} = \lim_{t \to \infty} \psi_{eff}(t)$

Test case (JB, Donnellan, Sommer, '11): PS static-light mesons, $N_f=0, a_s=a_t\sim 0.09 {\rm fm}, L\sim 1.5 {\rm fm}, m_q\sim m_s$

Ops. made from different smearings. Columns: m = 1..5, Rows: $r/r_0 = 0.0, 0.36, 0.62, 1.13$

Spatially Extended operators: (Basak, et al. '05), (Foley, et al. '07), (Dudek, et al. '08)

The Goal: For each symmetry channel pick a maximum energy.

Include an op. for each (known) state below that energy. J=0, I=0 (Isoscalar-scalar channel):

- single σ -meson operators
- single glueball operators
- I = 0 two pion operators, moving and at rest
- $\bar{K} K$ operators, moving and at rest
- ...

Needed even for isoscalar single hadrons

DISTILLATION

Exact smeared-smeared or point-smeared all-to-all propagators (Peardon, et al '09)

$$SQ^{-1}S = v_i K_{ij} v_j^{\dagger}$$

 $S = \sum_i^{N_{ev}} v_i^{\dagger} v_i, \ \Delta v_i = \lambda_i v_i$

CALCULATING THE EIGENPAIRS

Solution of N_t 3d eigenproblems of a hermitian operator.

Use a Krylov-Spectral Restarted Lanczos (KRSL) algorithm (Wu, Simon '00)

Chebyshev acceleration is very helpful

$$B = 1 + \frac{2(\tilde{\Delta} + \lambda_C)}{\lambda_L - \lambda_C}, \quad A = T_n(B)$$

Cost is dominated by global re-orthog. of the Krlov space.

$$\textit{Cost} \sim \textit{N}_{ev}^2 * \textit{N}_{itr} * \textit{V} \sim \textit{V}^4$$

Largest test: L = 3.8 fm, $N_{ev} = 384$, still a tiny fraction of the total cost.

Dominant cost is Dirac matrix inv.

Inv.cost
$$\sim N_{ev} * V \sim V^2$$

Results on small volumes (< 2.4 - 2.9 fm):

- N, Δ , and Ω baryons: (JB, et al. '10)
- $\pi\pi$ -scattering: (Dudek, et al. '12)
- ► Dπ-scattering: (Mohler, et al. '12)
- Kπ-scattering: (Lang, et al. '12)
- ρ and a_1 meson decay: (Prelovsek, et al. '11)

- I = 0 mesons: (Dudek, et al. '11)
- Charmonium: (Liu, et al. '11)
- Hybrid Baryons: (Dudek, Edwards '12)

Improvement when adding multi-hadron ops. (Prelovsek, et al. '12): $a_s = a_t = 0.12 \text{fm}, m_\pi = 266 \text{MeV}, L_s = 2 \text{fm}, D_0^*$ channel $(J^P = 0^+)$

STOCHASTIC LAPH

Introduce noise in the subspace (Morningstar, et al. '11)

$$\begin{split} \eta_{a\alpha}^{(r)}(\mathbf{x},t) &= \rho_{\alpha i}^{(r)}(t) v_{at}^{i}(\mathbf{x}) \\ SQ^{-1}S &= E_{r}(\psi\eta^{\dagger}), \ \psi^{(r)} = SQ^{-1}\eta^{(r)} \end{split}$$

Dilute in (α, i, t) -space:

$$\eta^{[d]} = P^{[d]}\eta, \ \psi^{[d]} = SQ^{-1}\eta^{[d]}, \ SQ^{-1}S = \sum_{d} E_r(\psi^{[d]}\eta^{[d]\dagger})$$

Correlator construction is simple and efficient!

- For connected lines: $N_{inv}/cfg. \sim 32 \times N_{t_0}$
- ▶ For disconnected lines: N_{inv}/cfg . ~ $32 \times 16 \times (0.03 {\rm fm}/a_t)$

Example: 4 connected lines, $N_{t_0} = 1$, $N_{inv}/cfg = 128$

$$\begin{split} \Omega_{ijk}(t_{0}) &= a_{\alpha\beta\gamma}^{abc} \sum_{\mathbf{x}_{0}} e^{i\mathbf{p}\cdot\mathbf{x}_{0}} \eta_{a\alpha}^{[i]}(x_{0}) \eta_{b\beta}^{[k]}(x_{0}) \eta_{b\gamma}^{[k]}(x_{0}) \\ \Sigma_{ijk}(t,t_{0}) &= a_{\alpha\beta\gamma}^{abc} \sum_{\mathbf{x}} e^{i\mathbf{p}\cdot\mathbf{x}} \psi_{a\alpha t_{0}}^{[i]}(x) \psi_{b\beta t_{0}}^{[j]}(x) \psi_{b\gamma t_{0}}^{[k]}(x) \\ \mathcal{A}_{ij}(t,t_{0}) &= \sum_{\mathbf{x}} \psi_{t_{0}}^{[i]\dagger}(x) \mathcal{A}_{0} \psi_{t_{0}}^{[j]}(x), \quad \omega_{ij}(t,t_{0}) = \sum_{\mathbf{x}} e^{i\mathbf{p}\cdot\mathbf{x}} \psi_{t_{0}}^{[i]\dagger}(x) \Gamma \psi_{t_{0}}^{[j]}(x) \\ \rho_{ij}(t_{0}) &= \sum_{\mathbf{x}_{0}} e^{i\mathbf{p}\cdot\mathbf{x}_{0}} \eta^{[i]\dagger}(x_{0}) \Gamma \eta^{[j]}(x_{0}) \end{split}$$

Correlation functions:

$$C_{\pi}(t-t_0) = \omega_{ij}\rho_{ij}, \ C_{f_{\pi}}(t-t_0) = \mathcal{A}_{ij}\rho_{ij}, \ C_{N}(t-t_0) = \Sigma_{ijk}\Omega^*_{ijk},$$

$$C_{\pi\pi}^{I=2}(t-t_0) = \omega_{ij} \ \rho_{jk} \ \omega_{k\ell} \ \rho_{\ell i} - C_{\pi}^2$$

STOCHASTIC LAPH AND QUARK-DISC. DIAGRAMS

Exact all-to-all is 'wasteful'(Wong, et al. '10):

- HSC Lattice: $N_f = 2 + 1$, $a_s = .12 \text{fm} = 3.5 a_t$, $m_{\pi} = 400 \text{MeV}$, $L_s = 1.9 \text{fm}$
- Left: 'Box' diagram for $\pi\pi$, Right: Disc. contribution to scalar
- For the scalar:
 - Distillation: $N_{inv}/cfg. = 16384$
 - Stochastic LapH: N_{inv}/cfg. = 1024

Scalar I = 0 channel (JB, D. Lenkner, et al. '11):

• HSC Lattice:
$$N_f = 2 + 1$$
, $a_s = .12 \text{fm} = 3.5 a_t$, $m_{\pi} = 400 \text{MeV}$, $L_s = 1.9 \text{fm}$

- ▶ 5x5 GEVP: 2 single meson ops., 2 $\pi\pi$ ops., 1 glueball op.
- Results of a preliminary diagonalization

CONCLUSIONS

- All-to-all propagators can be stochastically estimated efficiently
 - Effort \sim V with N_{inv} fixed, N_{inv}/cfg \sim 1200 is sufficient
 - Useful for 'ordinary' C(t), bare current insertions.
- First finite box spectrum calculations are underway: $a 0.9 - 0.12 \text{fm}, m_{\pi} > 260 - 300 \text{MeV}, L 2.5 - 3 \text{fm}$
- In principle, δ(k) below > 3 hadron thresholds can be extracted. At m_π ~ 300MeV, this covers interesting physics!
 - ▶ σ, f₀(980)
 - Roper resonance
 - A(1405)
- To Do:
 - Phase shifts above inelastic thresholds, similar issues to experiment

- smaller a, m_{π} , larger L
- Interaction with perturbative probes?
