**Integrable models** are characterized by a high amount of symmetry that usually makes them exactly solvable.

The Yang-Baxter equation signals the presence of integrable structures

 $R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12},$ 

 $R_{ij}=R_{ij}(u_i,u_j).$ 

The solution is called *R*-matrix and generates a tower of conserved charges.

# Definition (Integrable models)

Models characterized by an infinite tower of conserved charges  $Q_n$ 

 $[\mathbb{Q}_n, \mathbb{Q}_m] = 0, \quad n, m = 1, \dots, \infty, \quad \mathbb{Q}_2 = \mathbb{H}.$ 

*Examples*: Kepler's problem, Heisenberg spin chain, Hubbard model, AdS/CFT.

Applications: condensed matter, statistical physics, (quantum) field theory,

string theory and quantum information theory.

C. Paletta (Trinity College Dublin)

Free-fermion condition in the context of AdS/CFT

#### How to solve the Yang-Baxter equation?

- Algebraic approach: *R*-matrix exhibits some symmetries [Drinfeld, Faddeev, Kulish, Reshetikin, ...]
- Direct solution of YBE

[R.S. Vieira]

• Our approach: Reduce YBE to coupled ordinary differential equations. The transfer matrix

$$T(u,\theta) = \operatorname{tr}_0 \left( R_{0L}(u,\theta) \dots R_{01}(u,\theta) \right),$$

generates an infinite tower of commuting conserved charges

$$\log T(u,\theta) = \mathbb{Q}_1(\theta) + (u-\theta)\mathbb{Q}_2(\theta) + \frac{1}{2}(u-\theta)^2\mathbb{Q}_3(\theta) + \dots$$

$$\begin{split} R(u, u) &= P \text{ regular solution} \to nearest \text{ neighbour spin chain} \\ \log T(\theta, \theta) &= \mathbb{Q}_1(\theta) \sim \mathbb{P} \\ \mathbb{Q}_2 &= \mathbb{H}(\theta) = \sum_{n=1}^{L} P_{n,n+1} \frac{d}{du} R_{n,n+1}(u, \theta)|_{u \to \theta} \equiv \sum_n \mathcal{H}_{n,n+1}(\theta)_{or n} \\ &= \sum_{n=1}^{L} P_{n,n+1} \frac{d}{du} R_{n,n+1}(u, \theta)|_{u \to \theta} = \sum_n \mathcal{H}_{n,n+1}(\theta)_{or n} \\ &= \sum_{n=1}^{L} P_{n,n+1} \frac{d}{du} R_{n,n+1}(u, \theta)|_{u \to \theta} = \sum_n \mathcal{H}_{n,n+1}(\theta)_{or n} \\ &= \sum_{n=1}^{L} P_{n,n+1} \frac{d}{du} R_{n,n+1}(u, \theta)|_{u \to \theta} = \sum_n \mathcal{H}_{n,n+1}(\theta)_{or n} \\ &= \sum_{n=1}^{L} P_{n,n+1} \frac{d}{du} R_{n,n+1}(u, \theta)|_{u \to \theta} = \sum_{n=1}^{L} P_{n,n+1}(\theta)_{or n} \\ &= \sum_{n=1}^{L} P_{n,n+1} \frac{d}{du} R_{n,n+1}(u, \theta)|_{u \to \theta} = \sum_{n=1}^{L} P_{n,n+1}(\theta)_{or n} \\ &= \sum_{n=1}^{L} P_{n,n+1} \frac{d}{du} R_{n,n+1}(u, \theta)|_{u \to \theta} = \sum_{n=1}^{L} P_{n,n+1}(\theta)_{or n} \\ &= \sum_{n=1}^{L} P_{n,n+1} \frac{d}{du} R_{n,n+1}(u, \theta)|_{u \to \theta} = \sum_{n=1}^{L} P_{n,n+1}(\theta)_{or n} \\ &= \sum_{n=1}^{L} P_{n,n+1}(\theta)_{or n}$$

# Our approach

Bottom-up approach: Boost automorphism mechanism *Recipe*:

- 1) Consider a general nearest-neighbour Hamiltonian  $\begin{pmatrix} n_1(0) & 0 & 0 & n_8(0) \\ 0 & h_2(\theta) & h_6(\theta) & 0 \\ 0 & 0 & h_6(\theta) & h_3(\theta) & 0 \\ h_1(0) & h_2(\theta) & h_2(\theta) & h_2(\theta) \end{pmatrix}$ .
- 2) Use the boost operator  $\mathcal{B}[\mathbb{Q}_2]$  to generate the next conserved charge  $\mathbb{Q}_3(\theta)$ ,  $\mathcal{B}[\mathbb{Q}_2] := \partial_{\theta} + \sum_{n=-\infty}^{\infty} n\mathcal{H}_{n,n+1}$ ,  $\mathbb{Q}_3 \sim [\mathcal{B}[\mathbb{Q}_2], \mathbb{Q}_2]$ .
- 3) From  $[\mathbb{Q}_2(\theta), \mathbb{Q}_3(\theta)] = 0$ , solve a set of coupled first order, non-linear, differential equations for the entries of  $\mathcal{H}_{i,i+1}$ , so  $(h_i(\theta), 1 \le i \le 8)$ .
- 4) Plug the solutions in the  $\mathcal{H}_{i,i+1}(\theta)$ .

We need to find *R*-matrix whose logarithmic derivative is  $\mathcal{H}_{i,i+1}(\theta)$ 

5) Solve Sutherland equation  $[R_{13}R_{23}, \mathcal{H}_{12}(u)] = \dot{R}_{13}R_{23} - R_{13}\dot{R}_{23}$  to find *R*.

・ロト ・回ト ・ヨト ・ヨト … ヨ

Using this method, we classified *all possible regular* integrable spin-chains whose  $\mathcal{H}$  and *R*-matrix are of the form

$$\mathcal{H}(\theta) = \begin{pmatrix} h_1(\theta) & 0 & 0 & h_8(\theta) \\ 0 & h_2(\theta) & h_6(\theta) & 0 \\ 0 & h_5(\theta) & h_3(\theta) & 0 \\ h_7(\theta) & 0 & 0 & h_4(\theta) \end{pmatrix}, \qquad \mathcal{R}(u, v) = \begin{pmatrix} r_1(u, v) & 0 & 0 & r_8(u, v) \\ 0 & r_2(u, v) & r_6(u, v) & 0 \\ 0 & r_5(u, v) & r_3(u, v) & 0 \\ r_7(u, v) & 0 & 0 & r_4(u, v) \end{pmatrix}.$$
(1)

We found two classes of models characterized by the following entries of the Hamiltonian:

- A 6-Vertex  $h_6 \neq 0$  and  $h_7 = h_8 = 0$  A: Contains the usual XXZ and XYZ chain
  - 8-Vertex  $h_6 \neq 0$ ,  $h_7 \neq 0$   $h_8 \neq 0$
- B 6-Vertex  $h_6 = h_7 = h_8 = 0$  B: Contains  $AdS_2$  and  $AdS_3$ 
  - 8-Vertex  $h_6 = 0, h_7 \neq 0 h_8 \neq 0$

*R*-matrices of all these models satisfy the condition:  $\frac{(r_1r_4+r_2r_3-r_5r_6-r_7r_8)^2}{r_1r_2r_3r_4} = \text{const}$ const  $\neq 0$  Baxter condition (class A models), const = 0 Free-fermion condition (class B models).

#### For class B models 6-Vertex type

*Set-up*: 2 D space spanned by one boson  $|\phi\rangle$  and one fermion  $|\psi\rangle$ 

$$\begin{split} |\phi\rangle &\equiv |0\rangle, \quad |\psi\rangle \equiv c^{\dagger}|0\rangle, \quad c|0\rangle = 0, \\ \{c, c^{\dagger}\} &= 1, \quad \{c, c\} = \{c^{\dagger}, c^{\dagger}\} = 0, \quad c^{\dagger}c = n, \quad cc^{\dagger} = m. \\ R_{ij}^{(osc)}(u, v) &= r_{1}m_{i}m_{j} + r_{2}n_{i}m_{j} + r_{3}m_{i}n_{j} - r_{4}n_{i}n_{j} - r_{5}c_{i}c_{j}^{\dagger} + r_{6}c_{i}^{\dagger}c_{j} \\ \mathcal{H}_{ij}^{(osc)} &= P_{ij}\partial_{u}R_{ij}^{(osc)}(u, v)\Big|_{v=u} = \\ h_{1} + (h_{6} - h_{1})n_{j} - (h_{1} + h_{5})n_{i} - (h_{1} + h_{4} - h_{5} - h_{6})n_{i}n_{j} + h_{3}c_{j}^{\dagger}c_{i} + h_{2}c_{i}^{\dagger}c_{j}. \end{split}$$

Free-fermion condition on the level of the Hamiltonian:

$$h_1 + h_4 - h_5 - h_6 = 0.$$

How can we use the Free fermion condition to diagonalize the transfer matrix?

#### Homogeneous spin-chain of length N

# Canonical transformation $c_k = \frac{1}{\sqrt{N}} \sum_n e^{2\pi i \frac{kn}{N}} \eta_n$ , $c_k^{\dagger} = \frac{1}{\sqrt{N}} \sum_n e^{-2\pi i \frac{kn}{N}} \eta_n^{\dagger}$ ,

$$\mathbb{H} = \sum_{n=1}^{N} \mathcal{H}_{i,i+1} = h_1 N + \sum_{n=1}^{N} \left[ (h_2 + h_3) \cos \frac{2\pi n}{N} + i(h_2 - h_3) \sin \frac{2\pi n}{N} - h_1 + h_4 \right] \eta_n^{\dagger} \eta_n,$$

$$T = -\exp\left[A + \sum_{k} B_{k} N_{k}\right], \quad A = \log(r_{1}^{N} - r_{3}^{N}), \qquad B_{k} = \log\left[\frac{r_{2} + e^{\frac{2\pi i k}{N}} r_{4}}{r_{1} - e^{\frac{2\pi i k}{N}} r_{3}}\right].$$

Inhomogeneous spin-chain of length N

$$\begin{aligned} \boldsymbol{c}_{i}^{\dagger} &= \sum_{n} \frac{f_{i}(\boldsymbol{v}_{n}) \prod_{r=1}^{i-1} S_{r}(\boldsymbol{v}_{n})}{\sqrt{\sum_{r} f_{r}(\boldsymbol{v}_{n}) f_{r}^{*}(\boldsymbol{v}_{n})}} \eta_{n}^{\dagger}, \qquad \boldsymbol{c}_{i} &= \sum_{n} \frac{f_{i}^{*}(\boldsymbol{v}_{n}) \prod_{r=i}^{N} S_{r}(\boldsymbol{v}_{n})}{\sqrt{\sum_{r} f_{r}(\boldsymbol{v}_{n}) f_{r}^{*}(\boldsymbol{v}_{n})}} \eta_{n}, \\ \boldsymbol{T} &= -\exp\left[\boldsymbol{A} + \sum_{m=1}^{N} \boldsymbol{B}_{m} \boldsymbol{N}_{m}\right], \\ \boldsymbol{A} &= \log\left[\prod_{m=1}^{N} r_{1}(\boldsymbol{\theta}, \boldsymbol{\theta}_{m}) - \prod_{m=1}^{N} r_{3}(\boldsymbol{\theta}, \boldsymbol{\theta}_{m})\right], \qquad \boldsymbol{B}_{m} = \log\left[\frac{r_{3}(\boldsymbol{\theta}, \boldsymbol{v}_{m})}{r_{1}(\boldsymbol{\theta}, \boldsymbol{v}_{m})}\right]. \end{aligned}$$

Compact, elegant and useful form of the transfer matrix!

### Applications

 AdS<sub>3</sub>: additive structure to the eigenvalues of the transfer matrix is manifest

# Summary and Conclusion

- Using the boost authomorphism mechanism we *classified all regular* solutions of the YBE of 8-vertex type
- The class of solutions that contains holographic integrable models satisfy the *free fermion conditions*
- Using the free fermion condition we gave the expression of the *transfer matrix* of 6 Vertex type models for arbitrary number of sites and inhomogeneities

Thank you
