# NRQCD and the Laplace transform

- QCD expansion in  $p^2$
- Long history in phenomenology from late 1970's
- Agrees surprisingly well with experiment

$$G(\tau) = \int \frac{d\omega}{2\pi} K(\omega, \tau) \rho(\omega) d\omega = \text{Euclidean Correlation Function}$$

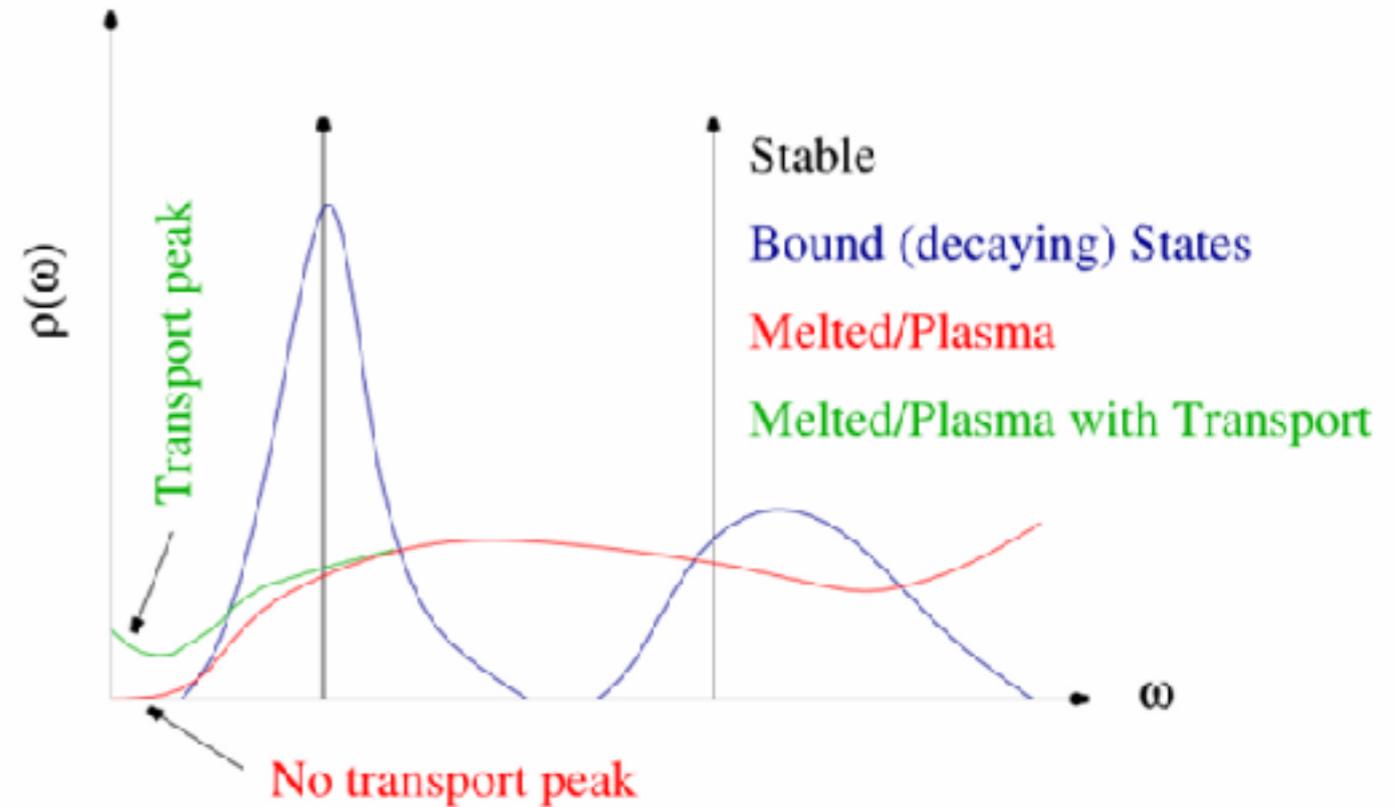

$$K(\omega, \tau) = e^{-\omega\tau} = \text{Kernel}$$

# Spectral Functions

$$G(\tau) = \int \frac{d\omega}{2\pi} K(\omega, \tau) \rho(\omega) d\omega$$

$\uparrow$  Euclidean Correlator  
 $\nearrow$  (Lattice) Kernel  
 $\downarrow$  Spectral Function

$$K(\omega, \tau) \sim e^{-\omega\tau} \quad \text{for NRQCD}$$

# Why bother?

Extracting  $\rho(\omega)$  crucial for:

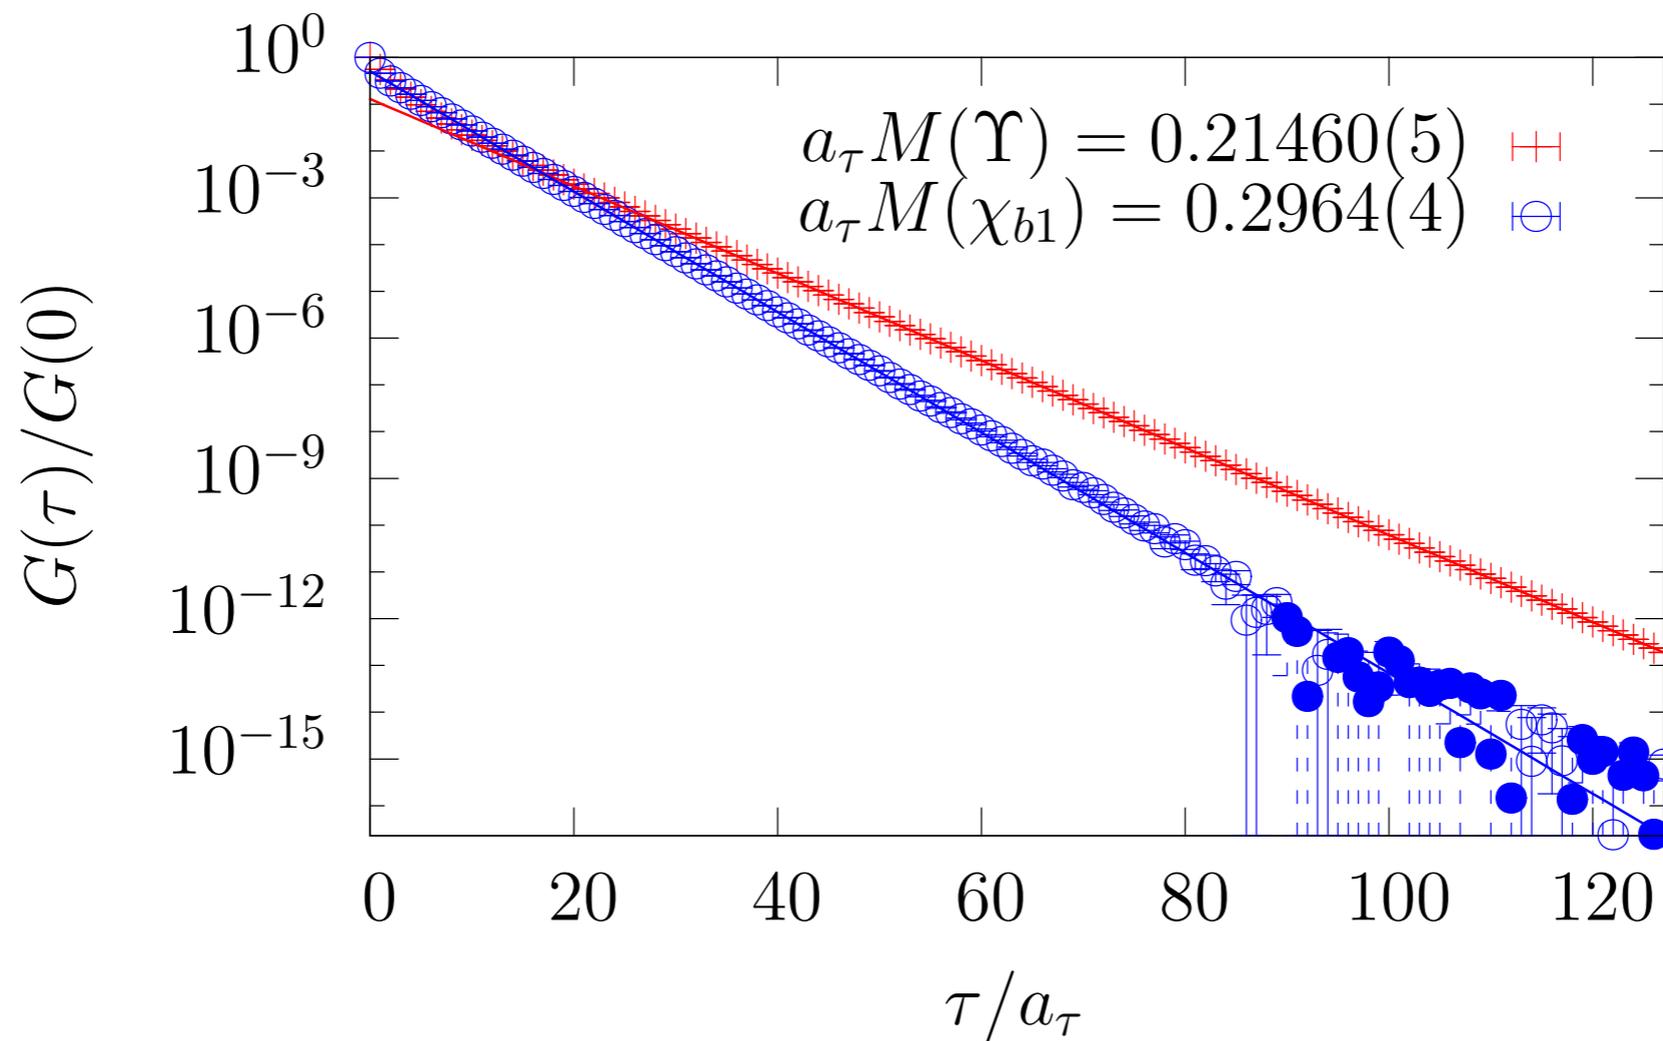

- masses
- widths
- “unbinding”

You may think it's easy, but...

# T=0 Correlators

## FASTSUM Generation 2

$$G(\tau) \equiv \sum_x \langle 0 | J(x, \tau) J^\dagger(0, 0) | 0 \rangle \xrightarrow[\gamma]{\tau \rightarrow \infty} \frac{|\langle 0 | J | \text{gnd} \rangle|^2}{2M} e^{-M\tau}$$

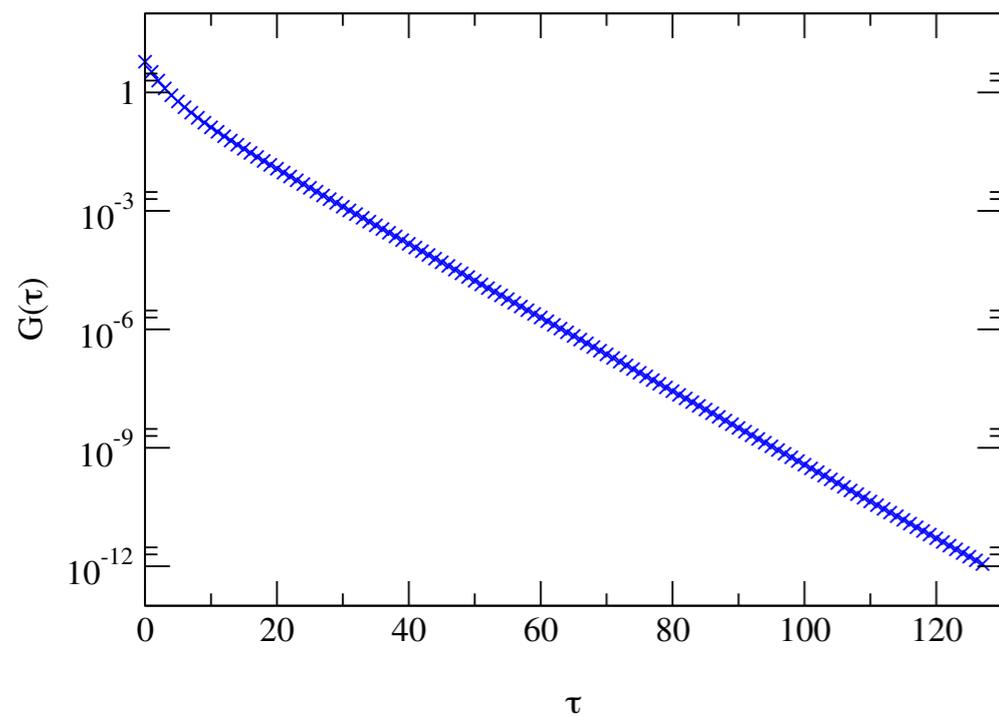

# Lattice Determinations of Quarkonia Width

## Extracting Spectral F'ns

Euclidean Lattice Correlator  $\rightarrow$   $G(\tau) = \int d\omega K(\omega, \tau) \rho(\omega) \leftarrow$  Spectral F'n

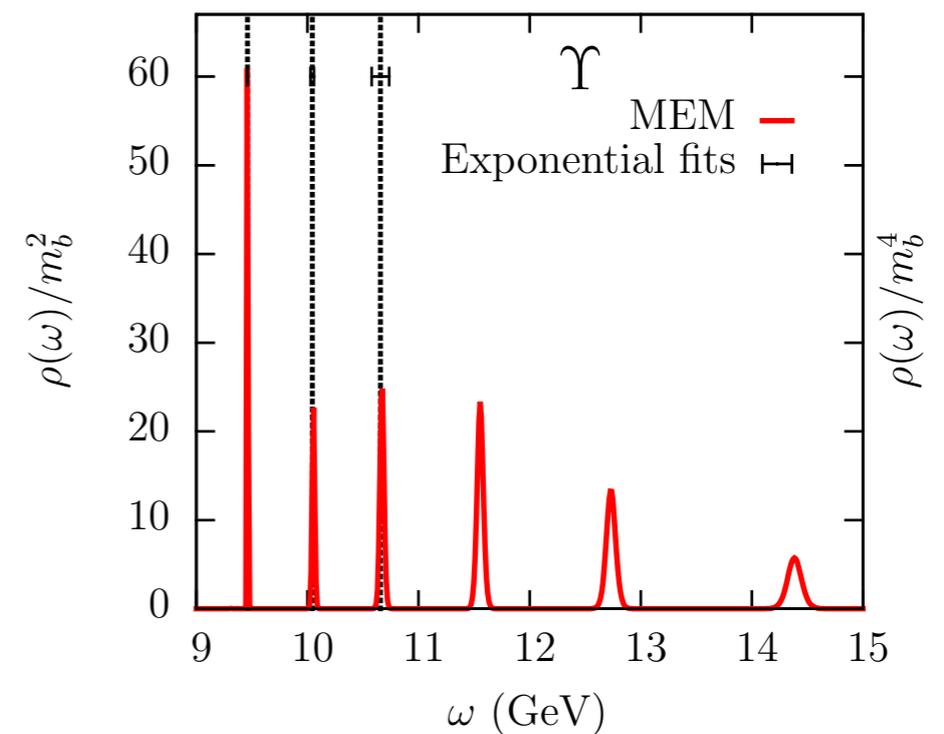

Input Data:

$$G_{\pm}(\tau)$$

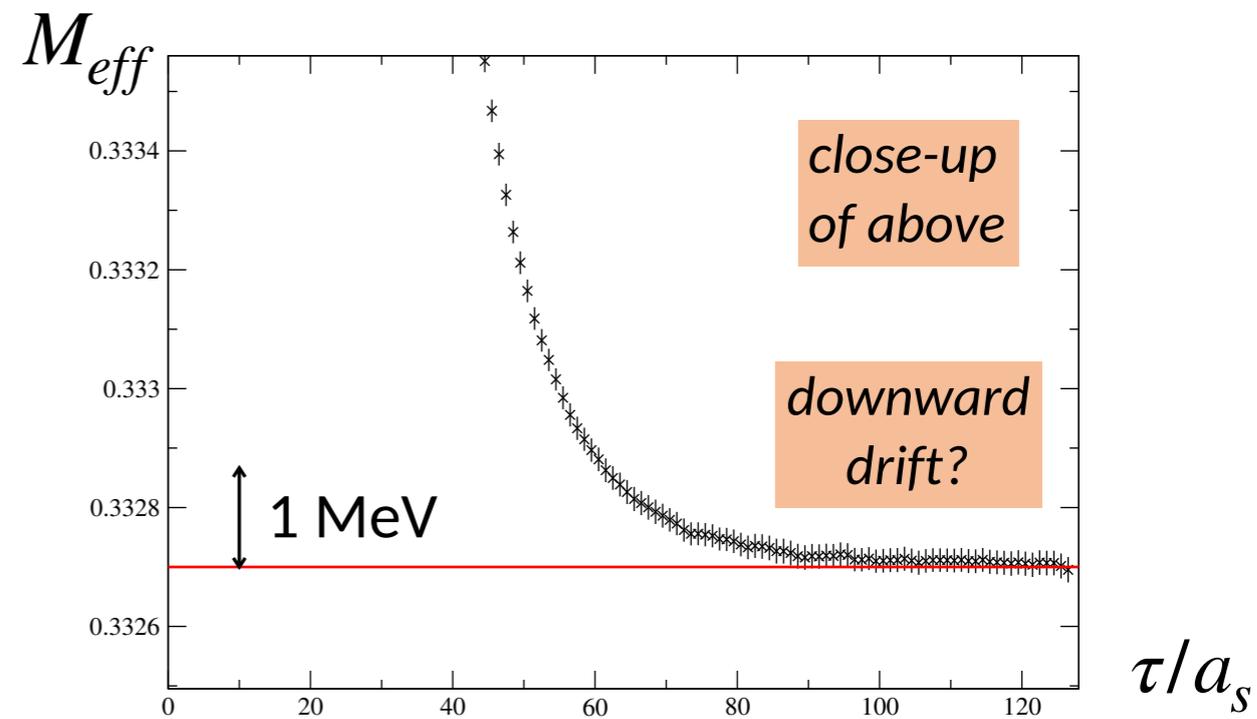

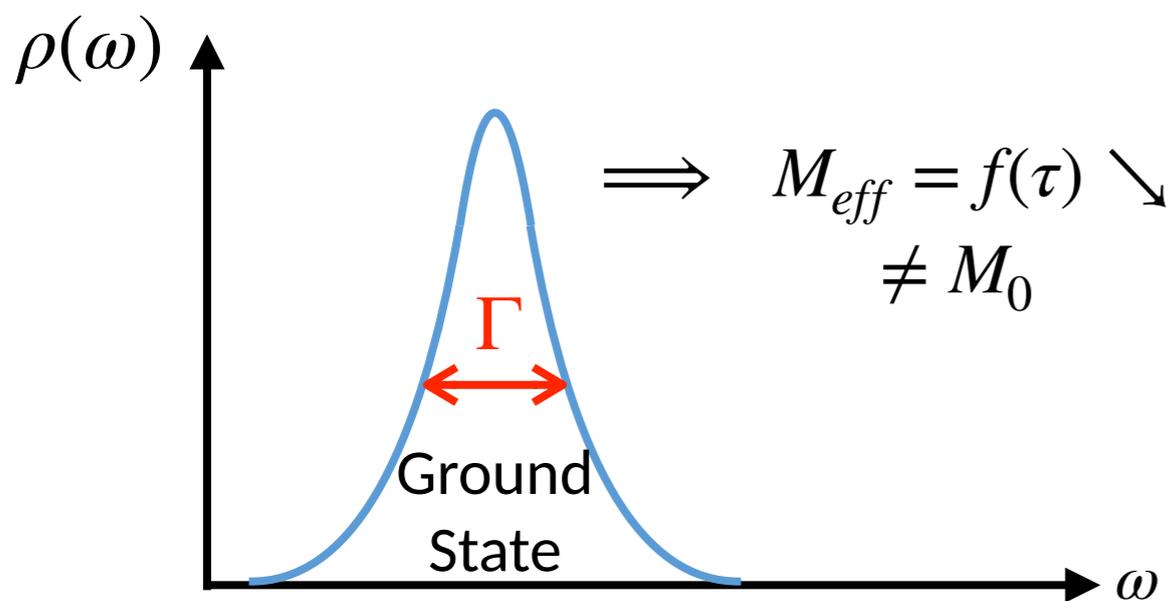

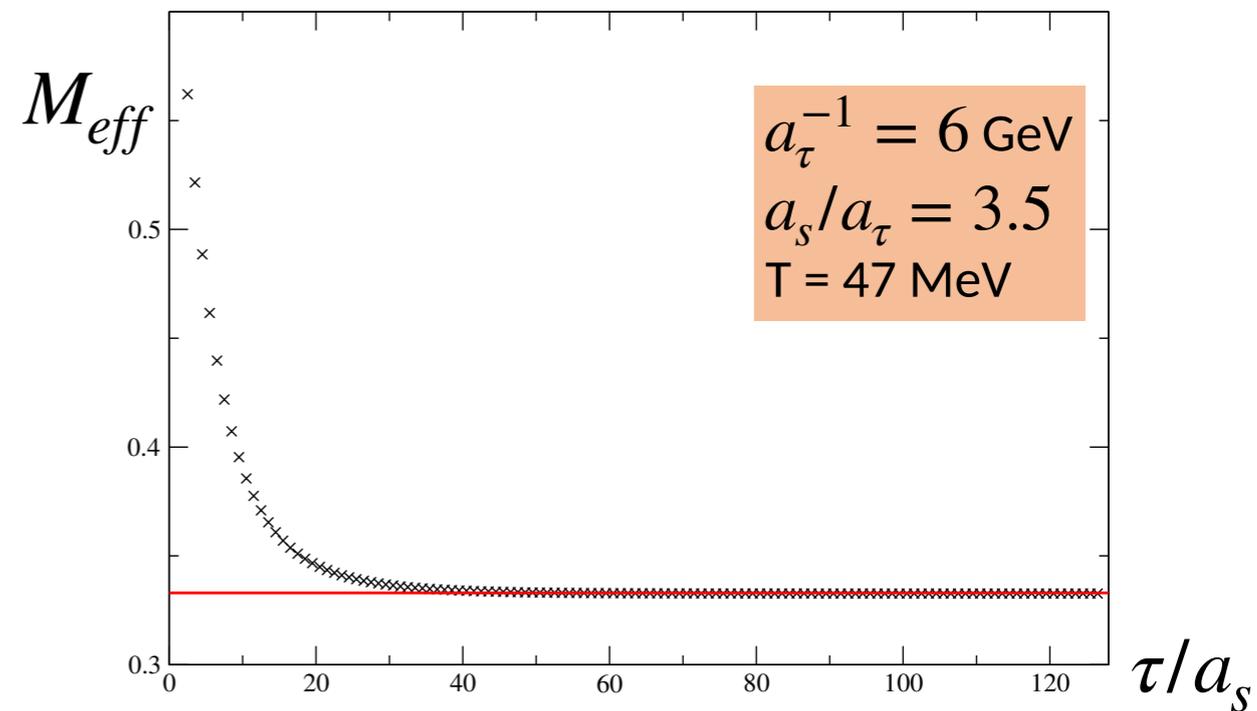

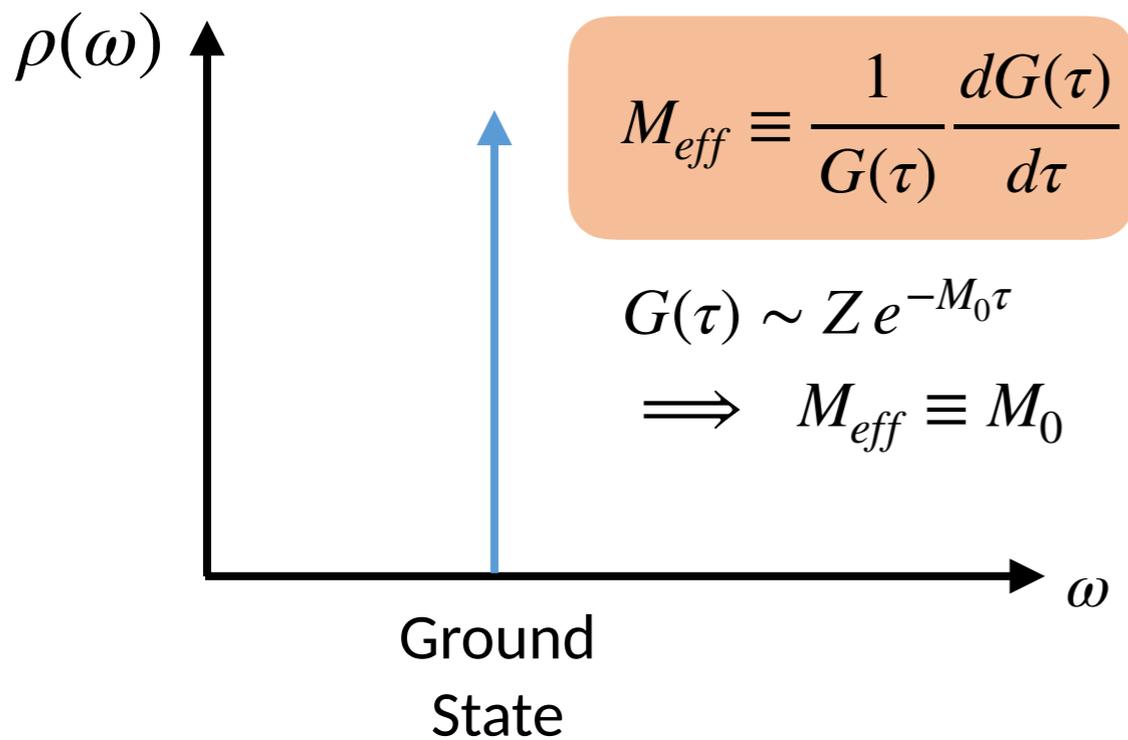

Output Data:

$$\rho_{\pm}(\omega)$$

# Thermal Case

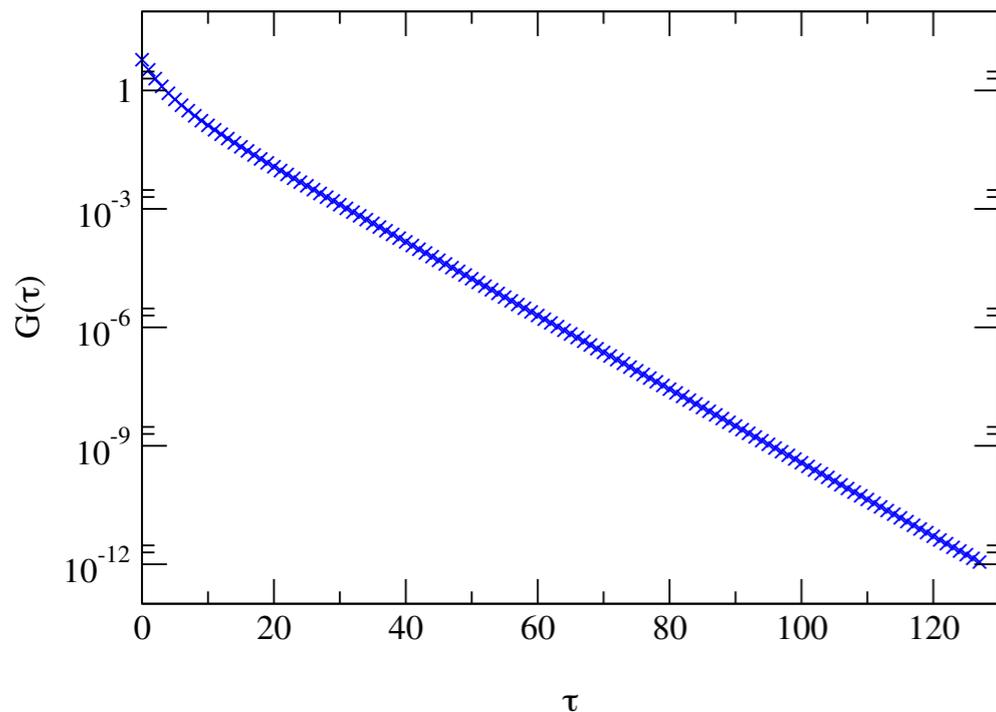

# Lattice Determinations of Quarkonia Width

## Extracting Spectral F'ns

Euclidean Lattice Correlator  $\rightarrow G(\tau) = \int d\omega K(\omega, \tau) \rho(\omega) \leftarrow$  Spectral F'n

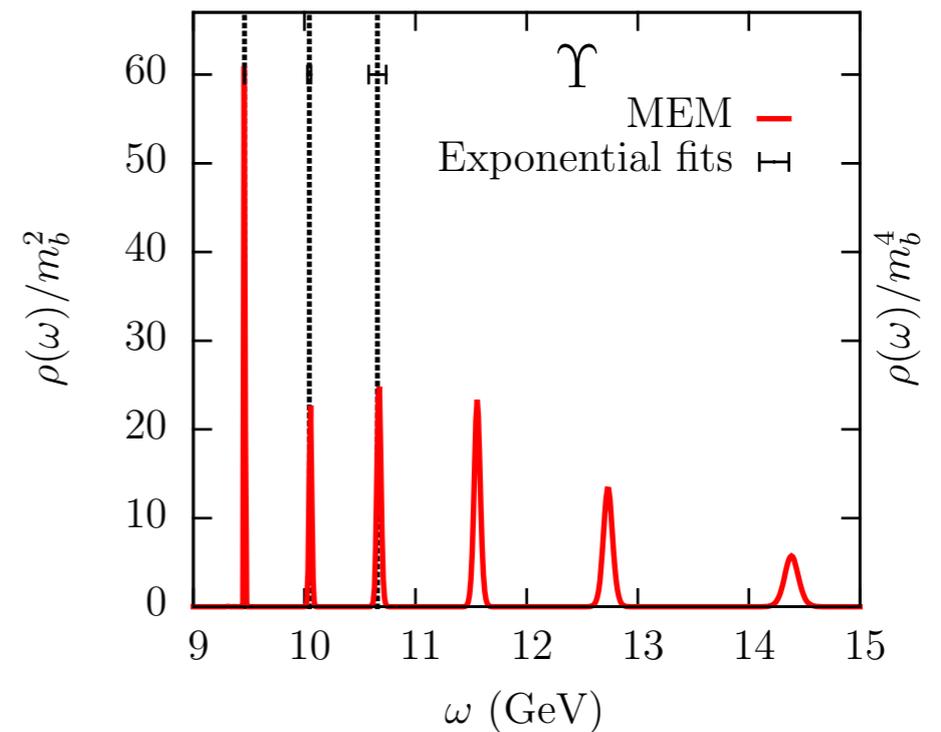

Input Data: **AND they are correlated!**

$G(\tau), \tau = 1, \dots, \mathcal{O}(10 - 100)$

Output Data:

$\rho_{\pm}(\omega), \omega \sim 1, \dots, \mathcal{O}(1000)$

**ill-posed! i.e.  $\infty$  solutions with  $\chi^2 = 0$**

An allegory of life: You can't get more out than you put in.

# Mathematical Limitations on Inverse Problem

McWhirter and Pike, J.Phys.A (1978) 1729

*On the numerical inversion of the Laplace transform...*

Cuniberti, De Micheli and Viano, Commun. Math. Phys. **216** (2001), 59-83

(courtesy of Mikko Laine)

Shuzhe Shia, Lingxiao Wang, Kai Zhou arXiv:2201.02564

Why is it difficult to extract  $\rho(\omega)$  from  $G(\tau)$  ?

- Is it because

$$G(\tau), \tau = 1, \dots, \mathcal{O}(10 - 100) \quad \rho_{\pm}(\omega), \omega \sim 1, \dots, \mathcal{O}(1000)$$

- (and) or something else?

# Mathematical Limitations on Inverse Problem

McWhirter and Pike, J.Phys.A (1978) 1729

*On the numerical inversion of the Laplace transform...*

Consider:  $G(\tau) = \int_0^{\infty} d\omega K(\omega\tau) \rho(\omega)$       **Note the product  $\omega \times \tau$**

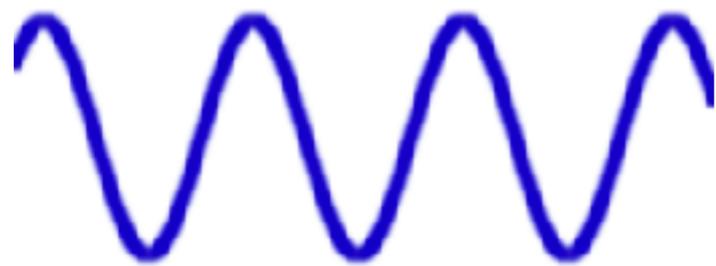

Note that Laplace transform has kernel of form:  $K(\omega\tau) = e^{-\omega\tau}$

Note relativistic kernel is not in this form:  $K(\omega, \tau) = \frac{\cosh(\omega(\tau - 1/2T))}{\sinh(\omega/2T)}$

Require that  $K(\omega\tau)$  is bounded:  $\int_0^{\infty} |K(x)| x^{-1/2} dx < \infty$

# Mathematical Limitations on Inverse Problem

View  $G(\tau) = \int_0^{\infty} d\omega K(\omega\tau) \rho(\omega)$  as a transformation

$G(\tau)$

time space

Fourier Transform

$\rho(\omega)$

frequency space

# Mathematical Limitations on Inverse Problem

Consider a perturbation (error) in  $\rho(\omega)$ :  $\delta\rho_{\Omega}(\omega) = \sin(\Omega\omega)$

This leads to a corresponding perturbation in  $G(\tau)$ :

$$\delta G(\tau) = \int K(\omega\tau) \sin(\Omega\omega) d\omega$$

Since  $K(\omega\tau)$  is integrable:  $\int K(\omega\tau) \sin(\Omega\omega) d\omega \longrightarrow 0$  as  $\Omega \rightarrow \infty$

ie.  $\delta G(\tau)$  can be made negligible!

Hence there are in  $\infty$  number of  $\rho(\omega)$  possible, i.e.  $\rho(\omega)$  is ***not unique!***

# Mathematical Limitations on Inverse Problem

McWhirter and Pike, J.Phys.A (1978) 1729

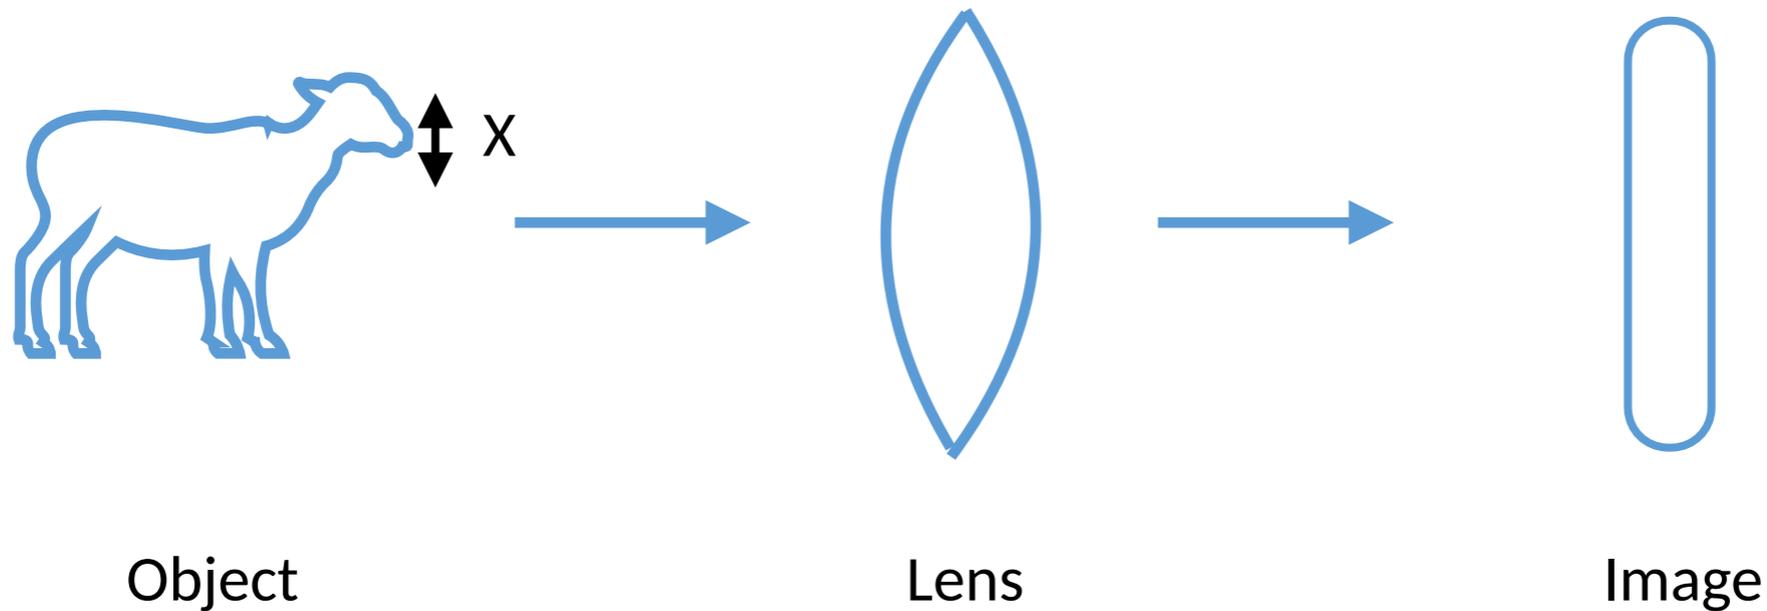

*On the numerical inversion of the Laplace transform...*

*“... This difficult numerical problem, which is frequently encountered by physicists and engineers, is still the subject of much attention”*

*“... need to consider information content in order to avoid obtaining meaningless results.”*

# Mathematical Limitations on Inverse Problem

Consider an optics example

$$I(x') = \frac{1}{2\pi} \int_{-\Omega}^{\Omega} d\omega e^{-i\omega x'} \int_{-X/2}^{X/2} e^{i\omega x} O(x) dx$$

where  $\Omega$  is the highest spatial frequency mode transmitted by lens

# Mathematical Limitations on Inverse Problem

$$I(x') = \frac{1}{2\pi} \int_{-\Omega}^{\Omega} d\omega e^{-i\omega x'} \int_{-X/2}^{X/2} e^{i\omega x} O(x) dx$$
$$= \int_{-X/2}^{X/2} \frac{\sin[\Omega(x' - x)]}{\pi(x' - x)} O(x) dx$$

Lens's highest spatial frequency mode has associate resolution limit of  $\pi/\Omega$

→ Concept of “**Information Content**” = No. of  $\pi/\Omega$  in Object

Hence Object of size  $X$  gives an Image with

$$S = \frac{X}{\pi/\Omega} \text{ independent d.o.f.} = \textit{Shannon Number} \text{ of Information Theory}$$

# Making Mathematical Progress on Inverse Problem

McWhirter and Pike, J.Phys.A (1978) 1729

Key concept is to cast inverse problem as eigenvalue problem

$$\int_{-X/2}^{X/2} \frac{\sin[\Omega(x' - x)]}{\pi(x - x')} \phi_n(x') dx' = \lambda_n \phi_n(x)$$

$\phi_n$  form complete orthogonal set.

$$I(x') = \sum_{n=0}^{\infty} b_n \phi_n(x') \quad \text{and} \quad O(x) = \sum_{n=0}^{\infty} a_n \phi_n(x')$$

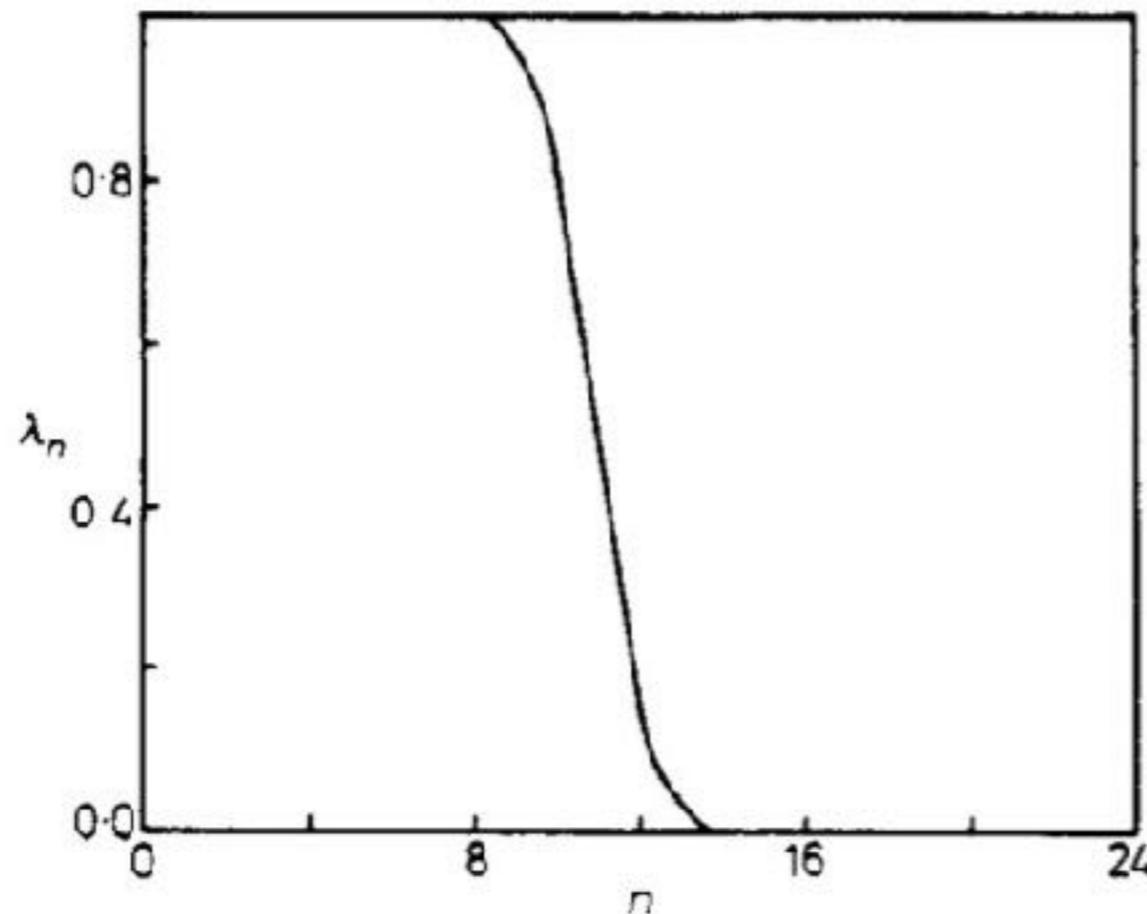

$$\text{Then } O(x) = \sum_{n=0}^{\infty} \frac{b_n}{\lambda_n} \phi_n(x)$$

**Looks easy... BUT....**

# Making Mathematical Progress on Inverse Problem

McWhirter and Pike, J.Phys.A (1978) 1729

*On the numerical inversion of the Laplace transform...*

$$\frac{X\Omega}{\pi} = 11.5$$

**Figure 2.** Eigenvalues  $\lambda_n$  of equation (2.7) as a function of  $n$ .

For other kernels/integral transforms,  $\lambda_n$  has similar features (but doesn't fall quite as fast)

# Making Mathematical Progress: Laplace Case

$$\text{Laplace Case: } \lambda_n \sim \sqrt{\frac{\pi}{\cosh(\pi n)}}$$

$$\text{Recall } O(x) = \sum_{n=0}^{\infty} \frac{b_n}{\lambda_n} \phi_n(x)$$

In general, we can write  $\rho(\omega)$  as

$$\rho(\omega) = \sum_{n=0}^N a_n \phi_n(\omega) + \sum_{n=N+1}^{\infty} \theta_n \phi_n(\omega)$$

“Knowable”  
 $\lambda \gg 0$

“Unknowable”  
 $\lambda \sim 0$

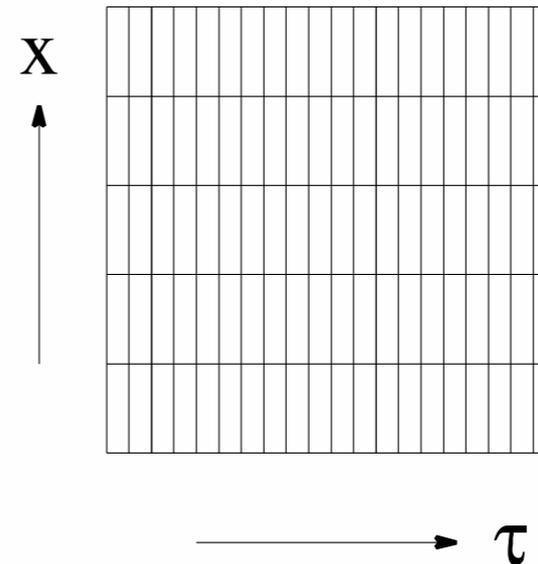

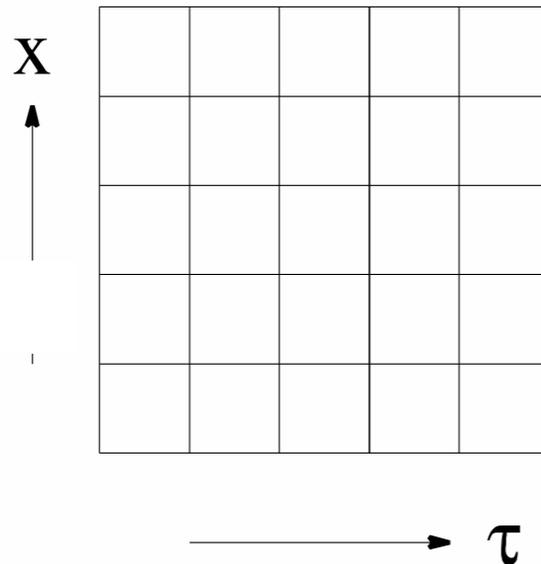

# FASTSUM setup

Anisotropic Lattice:

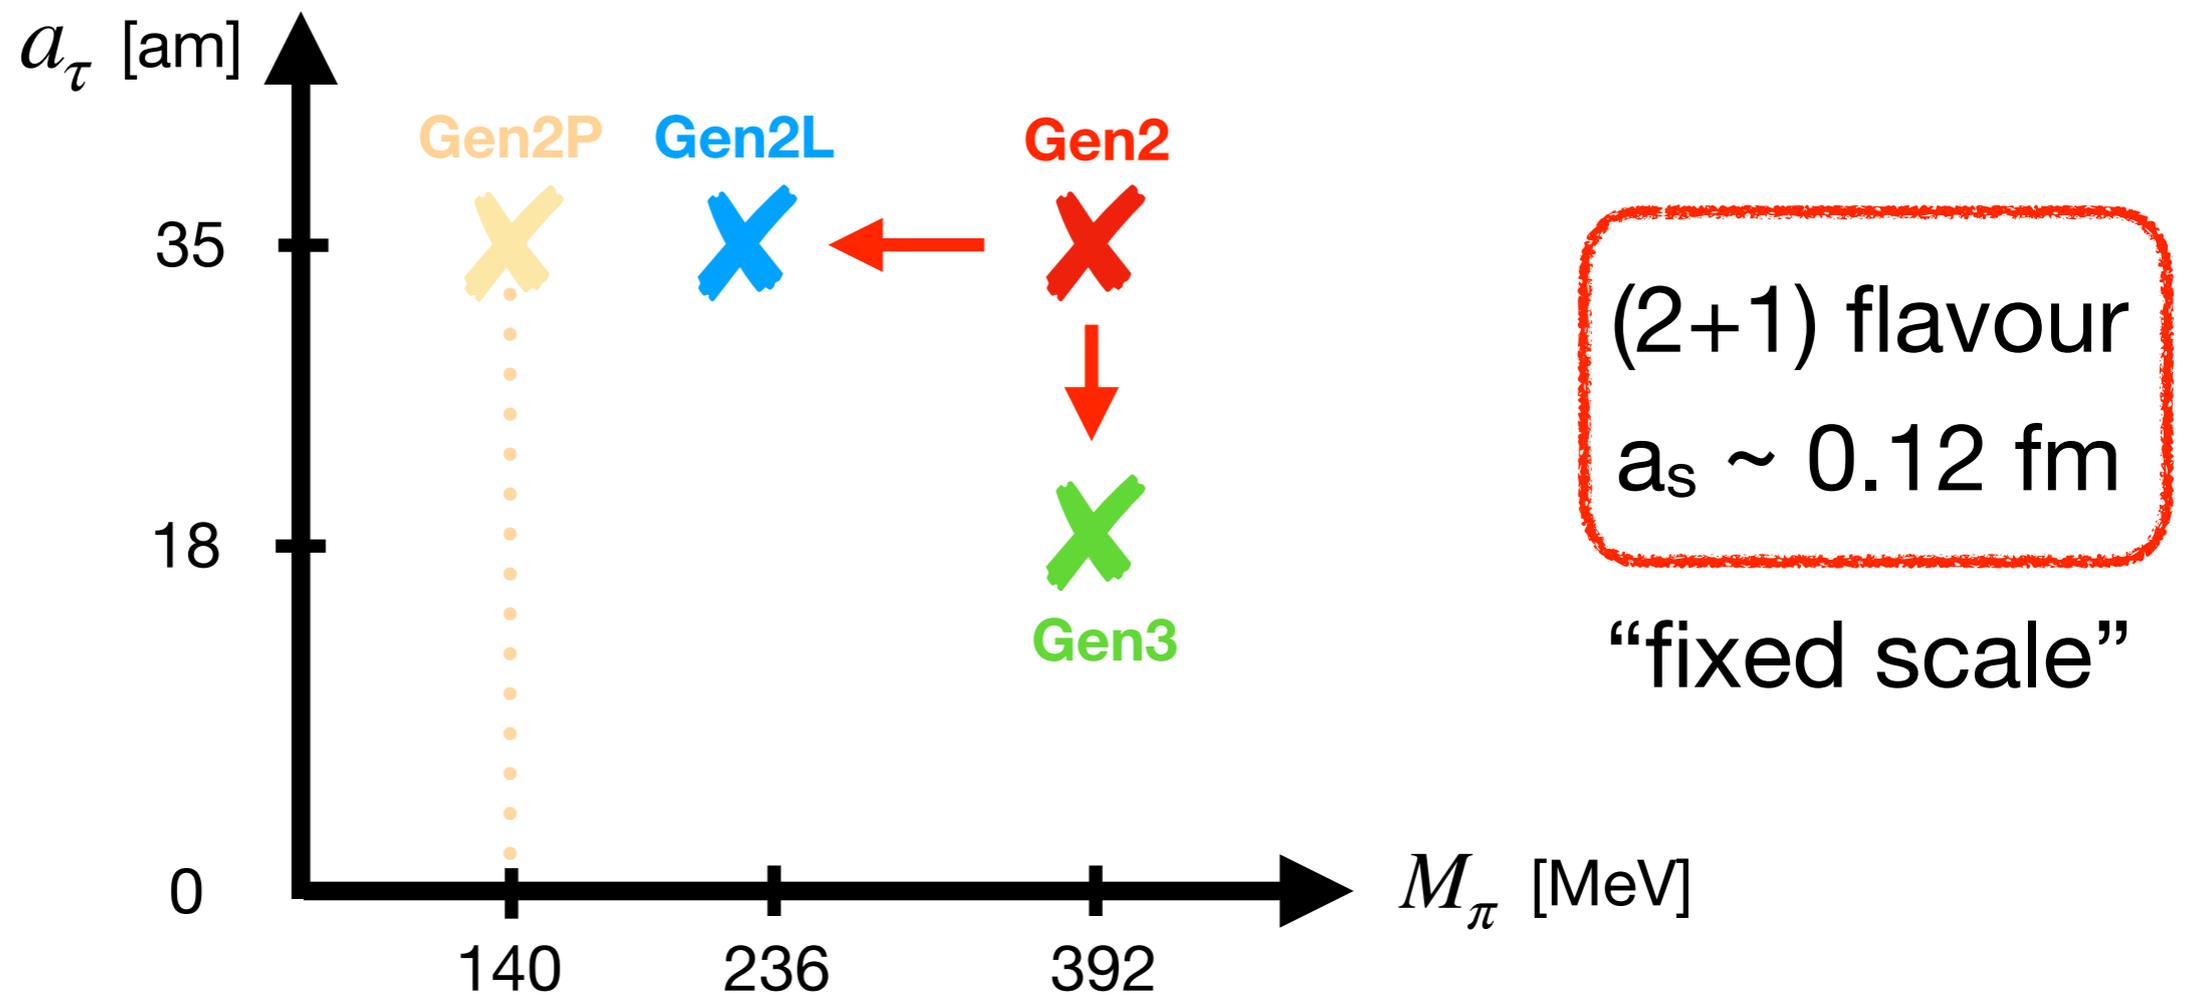

$$a_\tau < a_s$$

allowing for better resolution, particularly at finite temperatures, since

$$T = \frac{1}{L_\tau} = \frac{1}{N_\tau a_\tau}$$

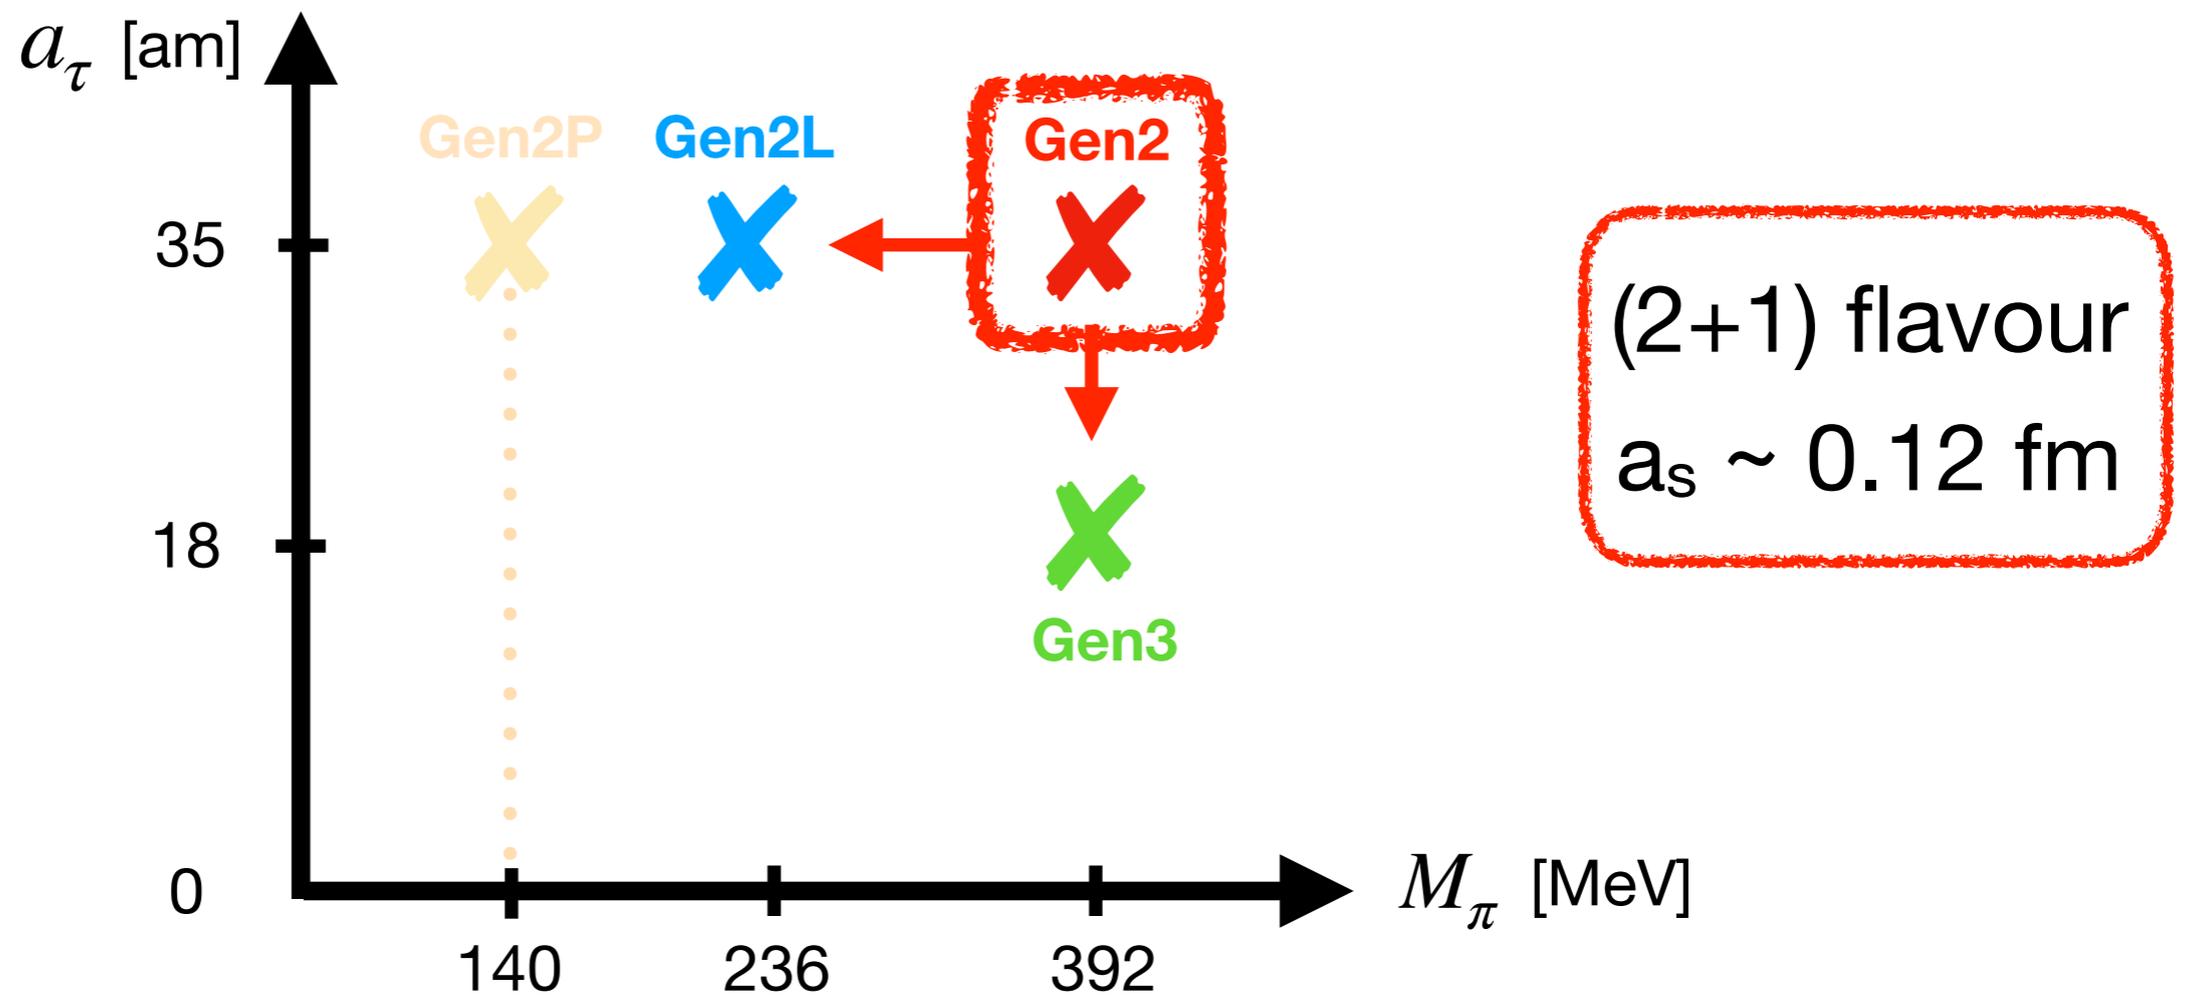

# Lattice Parameters

Going finer  $a_\tau \searrow$

Preliminary

# Study of Numerical Methods

1. Exponential (Conventional  $\delta$  f'ns)
  2. Gaussian Ground State (+  $\delta$  f'n excited)
  3. Moments of Correlation F'ns
  4. BR Method
  5. Maximum Entropy Method
  6. Kernel Ridge Regression
  7. Backus Gilbert
- Maximum Likelihood  
(Minimise  $\chi^2$ )
- Direct Method - "no" fit
- Bayesian Approaches
- Machine Learning
- from Geophysics

# Moments

$$G(\tau) = \int e^{-\omega\tau} \rho(\omega) d\omega \quad \longrightarrow \quad \frac{dG(\tau)}{d\tau} = \int \omega e^{-\omega\tau} \rho(\omega) d\omega$$

$$-\frac{1}{G(\tau)} \frac{dG(\tau)}{d\tau} = M_{eff}(\tau) = \frac{1}{G(\tau)} \int \omega e^{-\omega\tau} \rho(\omega) d\omega = \langle \omega \rangle_{e^{-\omega\tau} \rho(\omega)}$$

Similarly, we can take a 2nd derivative to calculate

Variance (i.e. width):

$$\Gamma^2 = \frac{1}{G(\tau)} \frac{d^2 G(\tau)}{d\tau^2} - M_{eff}^2 = \langle (\omega - \langle \omega \rangle)^2 \rangle$$

# Thomas Bayes 1701 - 1761

- Religious Minister
- Did not publish Bayes Theorem

# Richard Price 1723 - 1791

- Born in Wales
- Educated in Neath
- Also a religious minister
- Published Bayes Theorem after Bayes death
- Friends and proponent of American Independence Leaders, Benjamin Franklin, Thomas Jefferson, George Washington

# Bayesian Approaches

Need to maximise  $P(F | D)$

Bayes Theorem :

$$P(F \cap D) = P(F | D) P(D) = P(D | F) P(F)$$

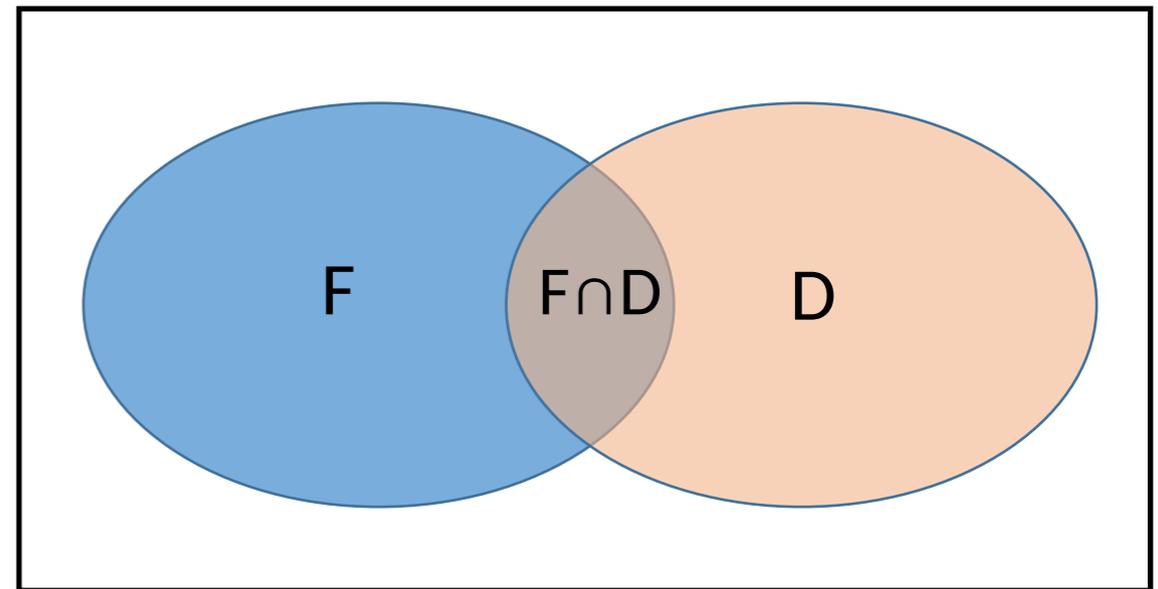

$$\text{i.e. } P(F | D) = \frac{P(D | F) P(F)}{P(D)}$$

Note  $P(D | F) \sim \chi^2$

So we should always include  $P(F)$  = “Priors”

$P(F)$  is encoded as an *Entropy*

BR and MEM use different Entropy definitions

# Bayesian Approaches

Bayes's Theorem: 
$$P(F | D) = \frac{P(D | F) P(F)}{P(D)}$$

Is “Maximum Likelihood” method wrong because we don't include  $P(F)$  = “Priors” ?

In fact we **do** include priors in Maximum Likelihood method in our choice of fitting f'n

e.g.  $f(\tau) = Z e^{-M\tau}$

So we are always including prior information...

The Prior is a way of regulating the Inverse Problem and removing degeneracies.

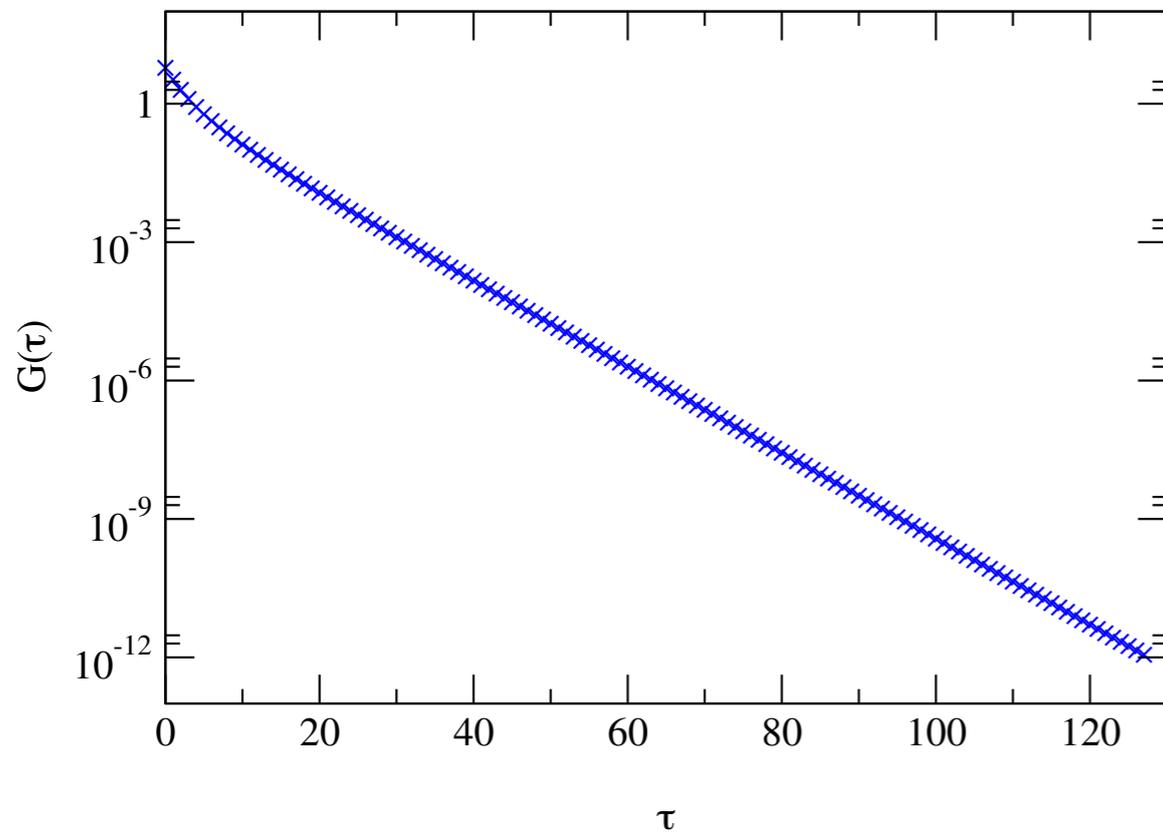

# Entropy

	No Data	Data
No Prior	$\mathcal{I}(F) \equiv 0$	$F$ from $\min \chi^2$
Prior	$F \equiv \text{prior}$	$F$ from $\max P(F D)$

# Extracting Spectral Functions

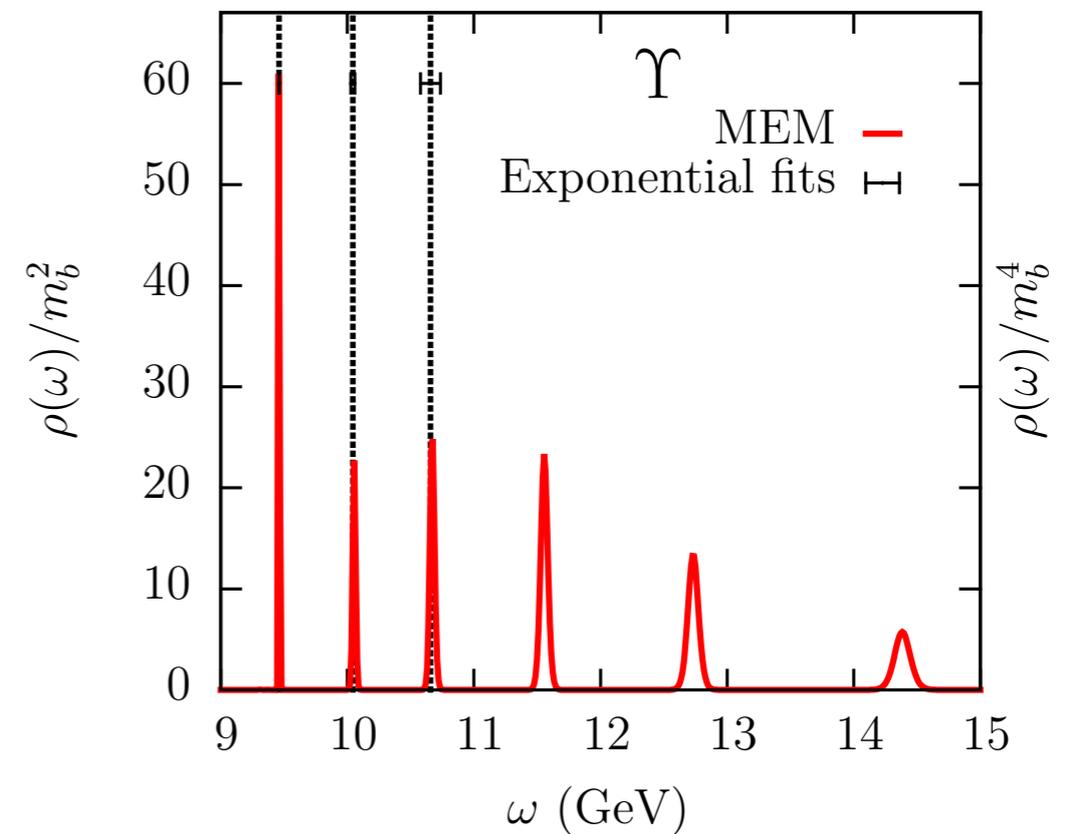

Input Data:

$$G_{\pm}(\tau), \quad \tau = 1, \dots, \mathcal{O}(10 - 100)$$

Output Data:

$$\rho_{\pm}(\omega), \quad \omega \sim 1, \dots, \mathcal{O}(1000)$$

***ill-posed !      i.e.  $\infty$  solutions with  $\chi^2 = 0$***

“Entropy” Factor  $P(F)$  breaks this degeneracy

# Choice of Entropy Term

$$P(F) \sim e^S \quad S = \text{Entropy}$$

## Maximum Entropy Method:

*Shannon-Jaynes Entropy:*

$$S = \int_0^\infty d\omega \left[ \rho(\omega) - m(\omega) - \rho(\omega) \ln \frac{\rho(\omega)}{m(\omega)} \right]$$

Asakawa, Hatsuda, Nakahara, Prog.Part.Nucl.Phys. 46 (2001) 459

## BR Method:

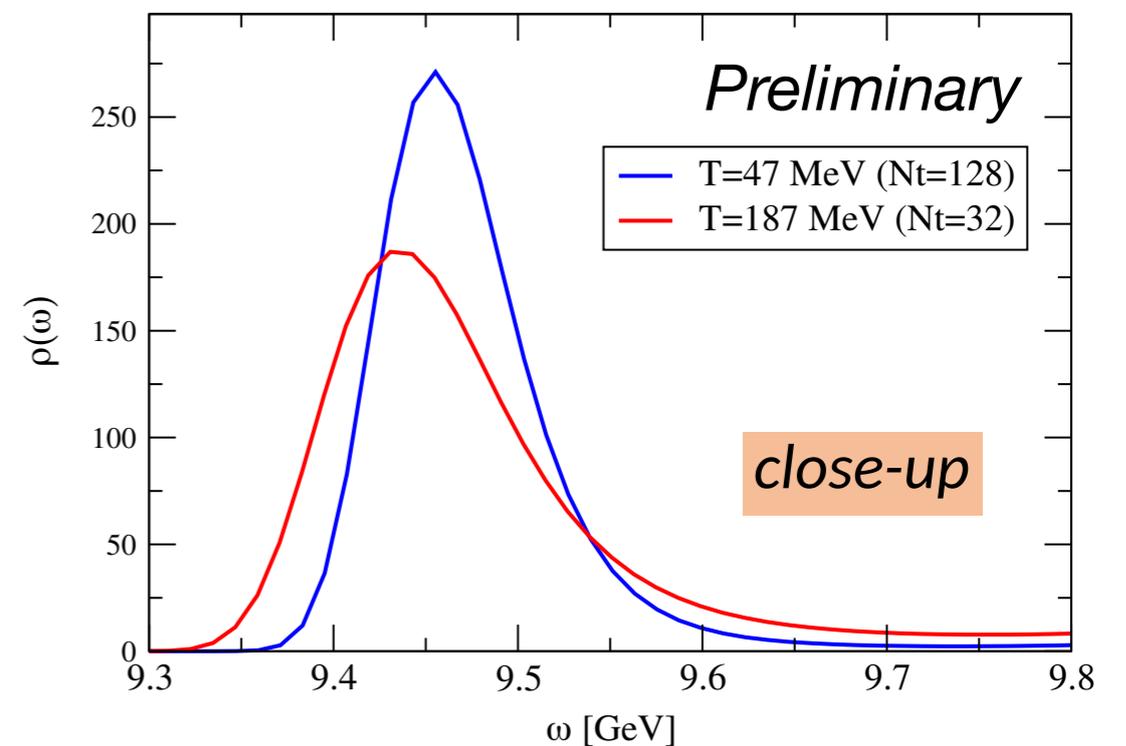

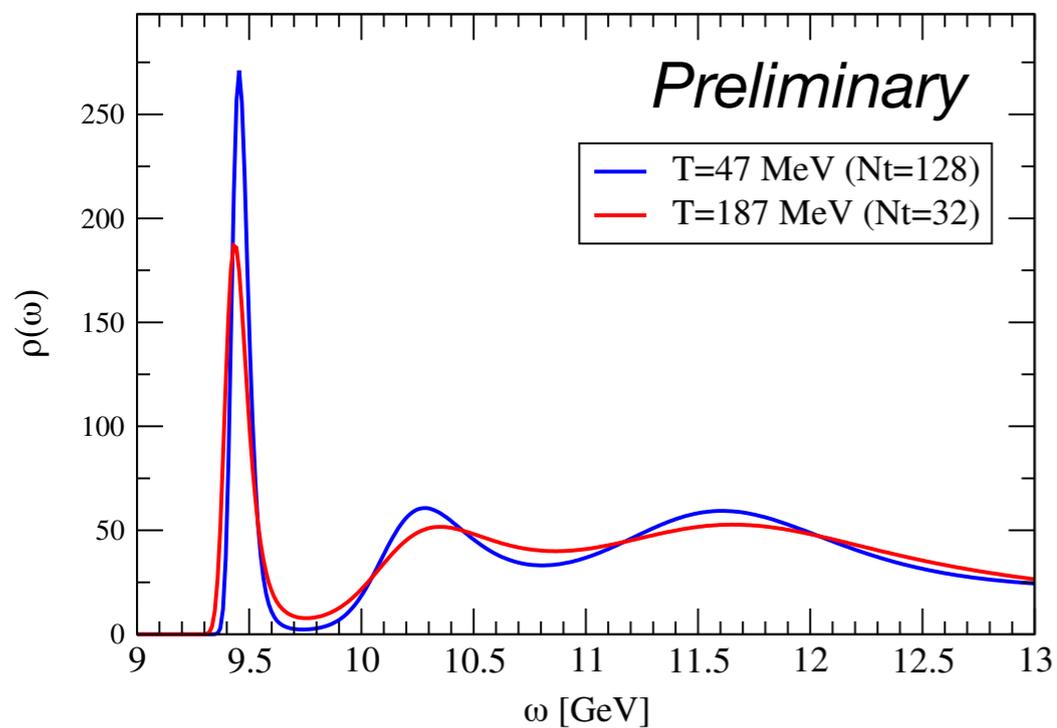

$$S = \int_0^\infty d\omega \left[ 1 - \frac{\rho(\omega)}{m(\omega)} + \ln \frac{\rho(\omega)}{m(\omega)} \right]$$

Burnier & Rothkop Phys.Rev.Lett. 111 (2013) 182003

# Apples and Apples

Systematic effects in  $T$  (MEM)

Fitting:  $\tau = [2,30]$  for both  $T$

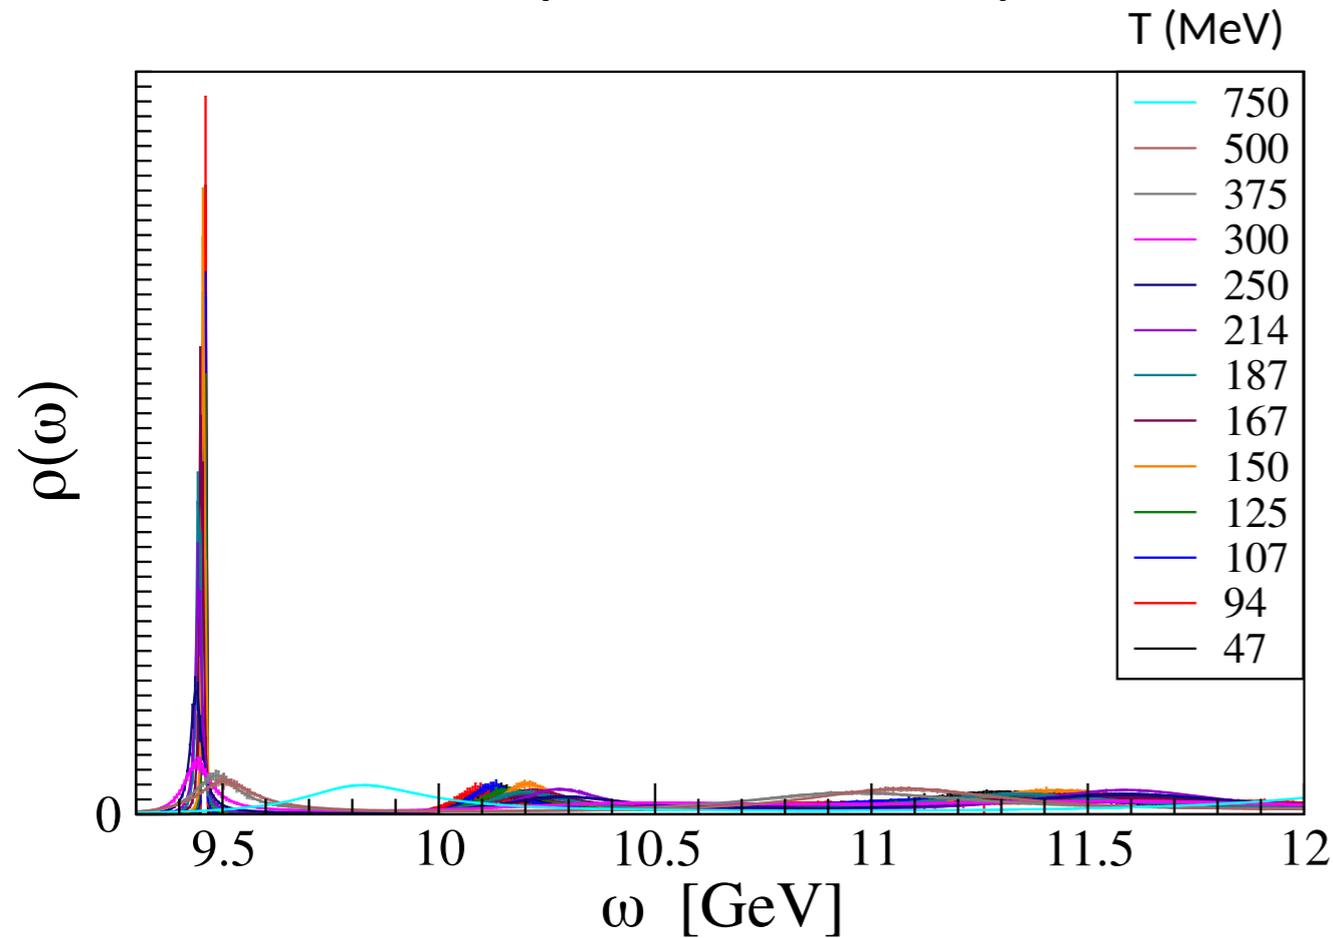

Sequential suppression

$\Gamma \nearrow$  as  $T \nearrow$

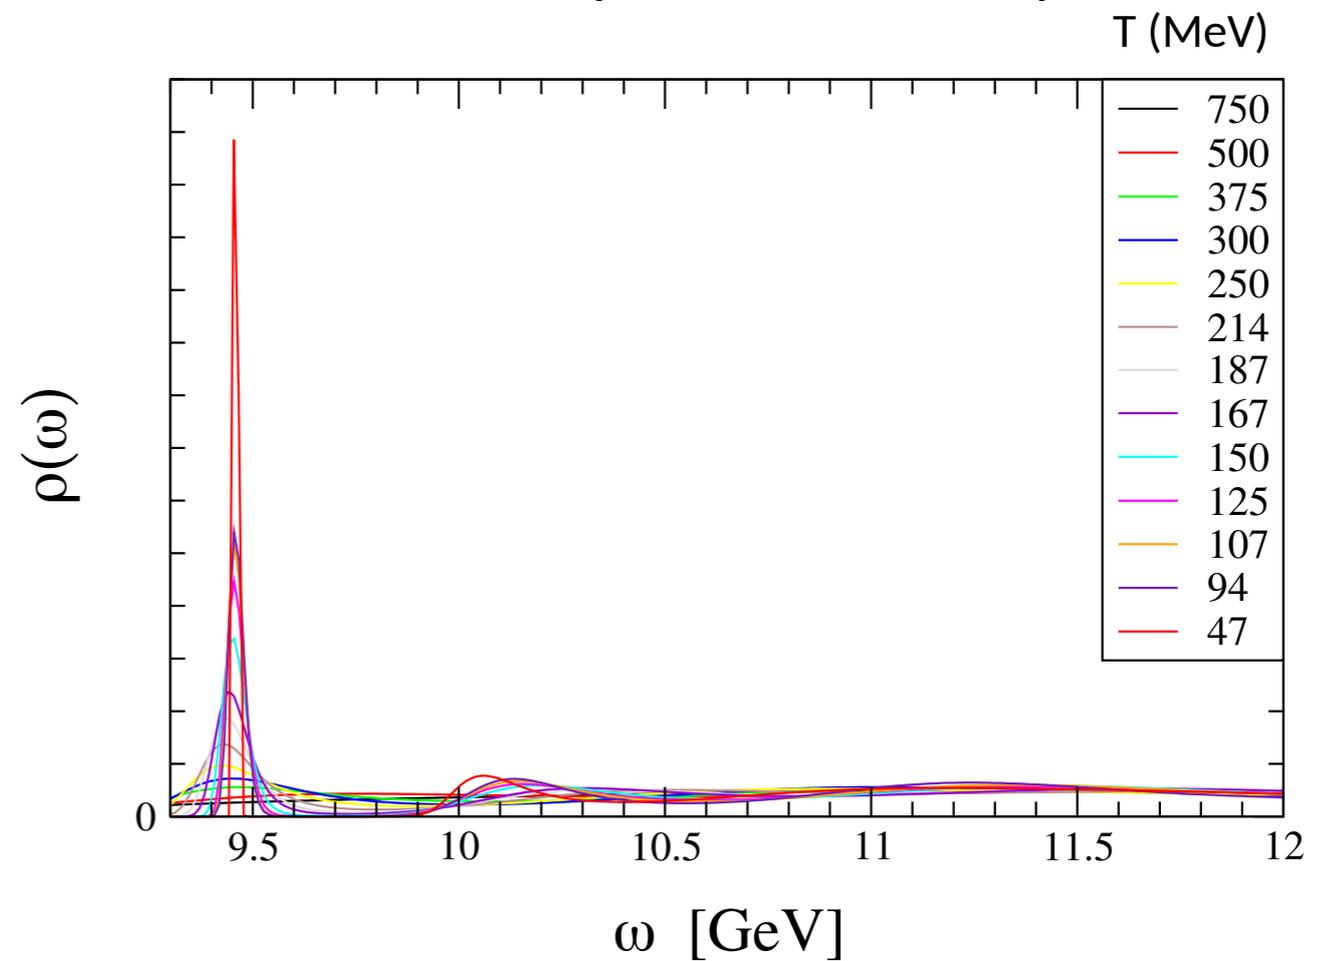

Although  $\Gamma$  is *upper bound*, we can resolve thermal trends

# Direct comparison of Bayesian Approaches

BR Upsilon Preliminary

MEM Upsilon Preliminary

# Kernel Ridge Regression

## Machine Learning

- uses training data to determine an *alpha matrix* of parameters determined analytically using a cost function
- cost function includes a term to prevent overfitting
- training data set is  $\mathcal{O}(10^4)$  mock data with 5 Gaussians
- difficult to produce systematic error estimate

# Backus Gilbert

Take  $G(\tau) = \int \rho(\omega) e^{-\omega\tau} d\omega = \int \rho(\omega) K(\omega, \tau)$

Generate *averaging functions*:  $A(\omega, \omega_0) = \sum_{\tau} c_{\tau} K(\omega, \tau)$

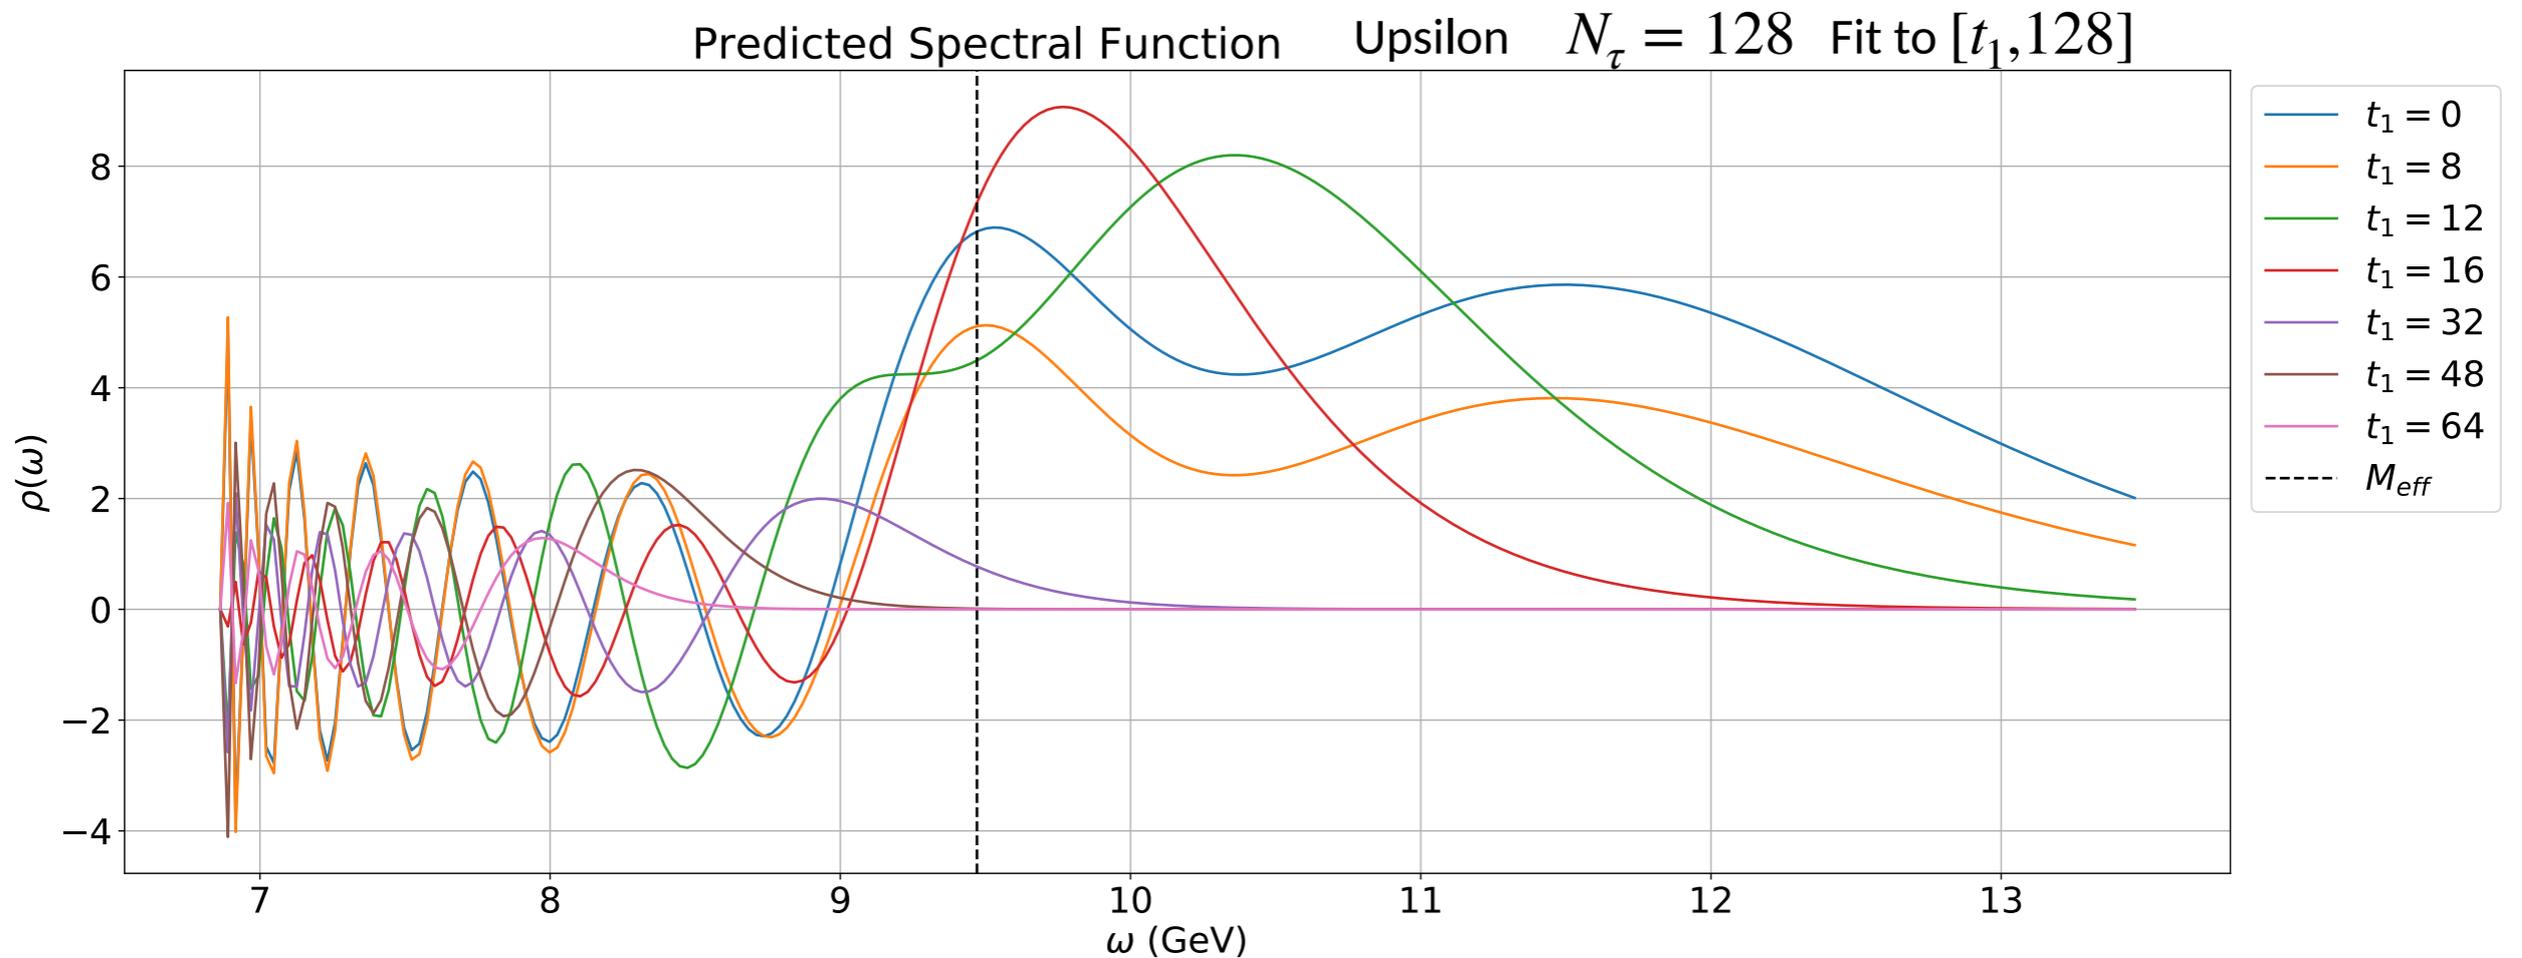

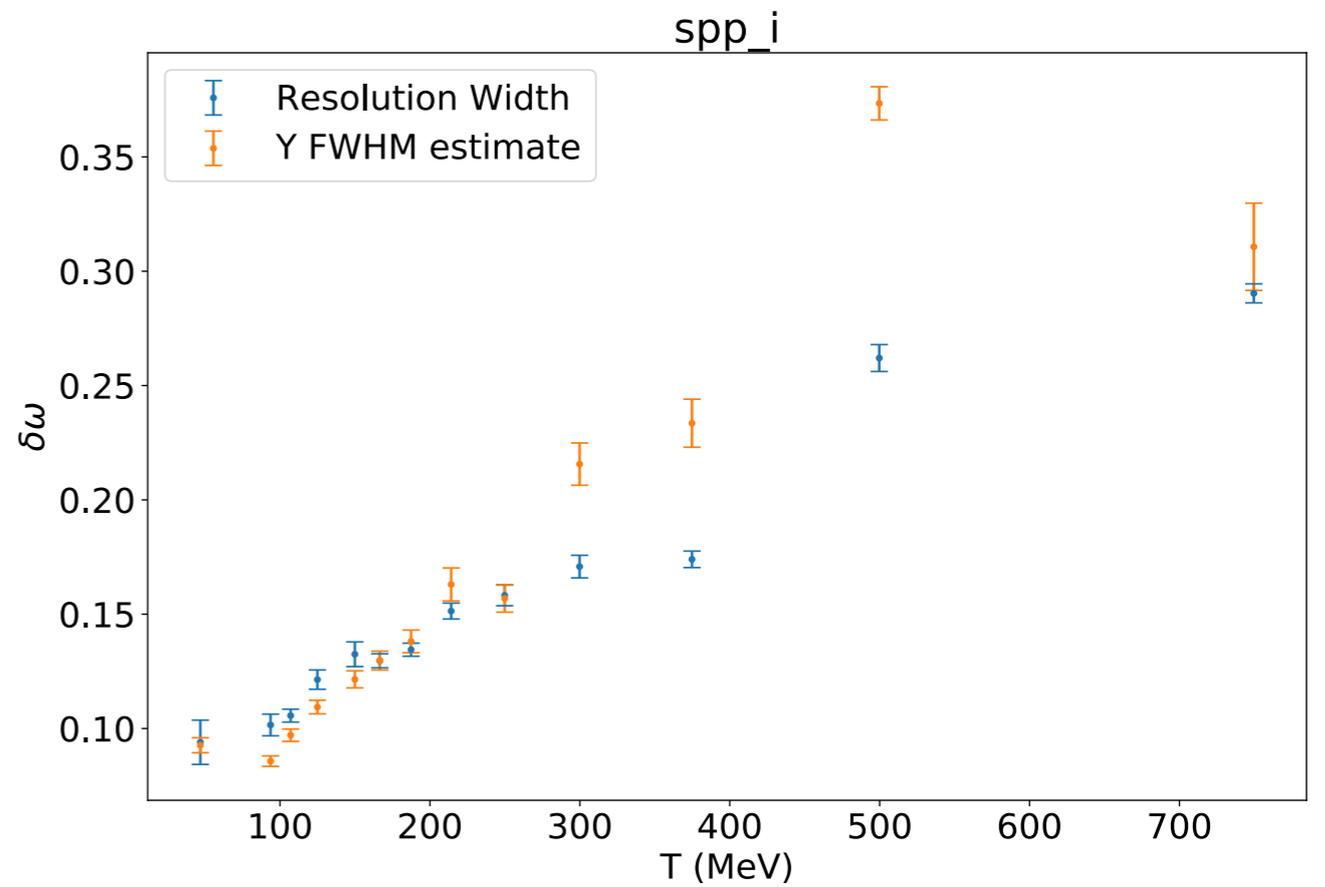

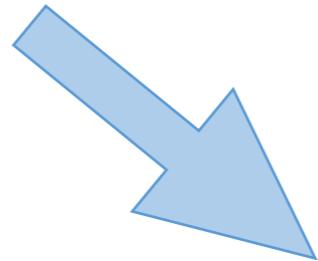

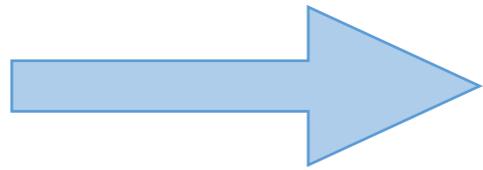

(an approximation to the  $\delta$  f'n), such that

$$\begin{aligned}\hat{\rho}(\omega_0) &= \int A(\omega, \omega_0) \rho(\omega) d\omega \\ &= \sum_{\tau} c_{\tau} G(\tau) \\ &\approx \rho(\omega_0)\end{aligned}$$

Averaging coeffs  $c_{\tau}$  determined by *minimising the width* of  $A(\omega, \omega_0)$

# Backus Gilbert Systematics

- Intrinsic Resolution
- Time window systematics

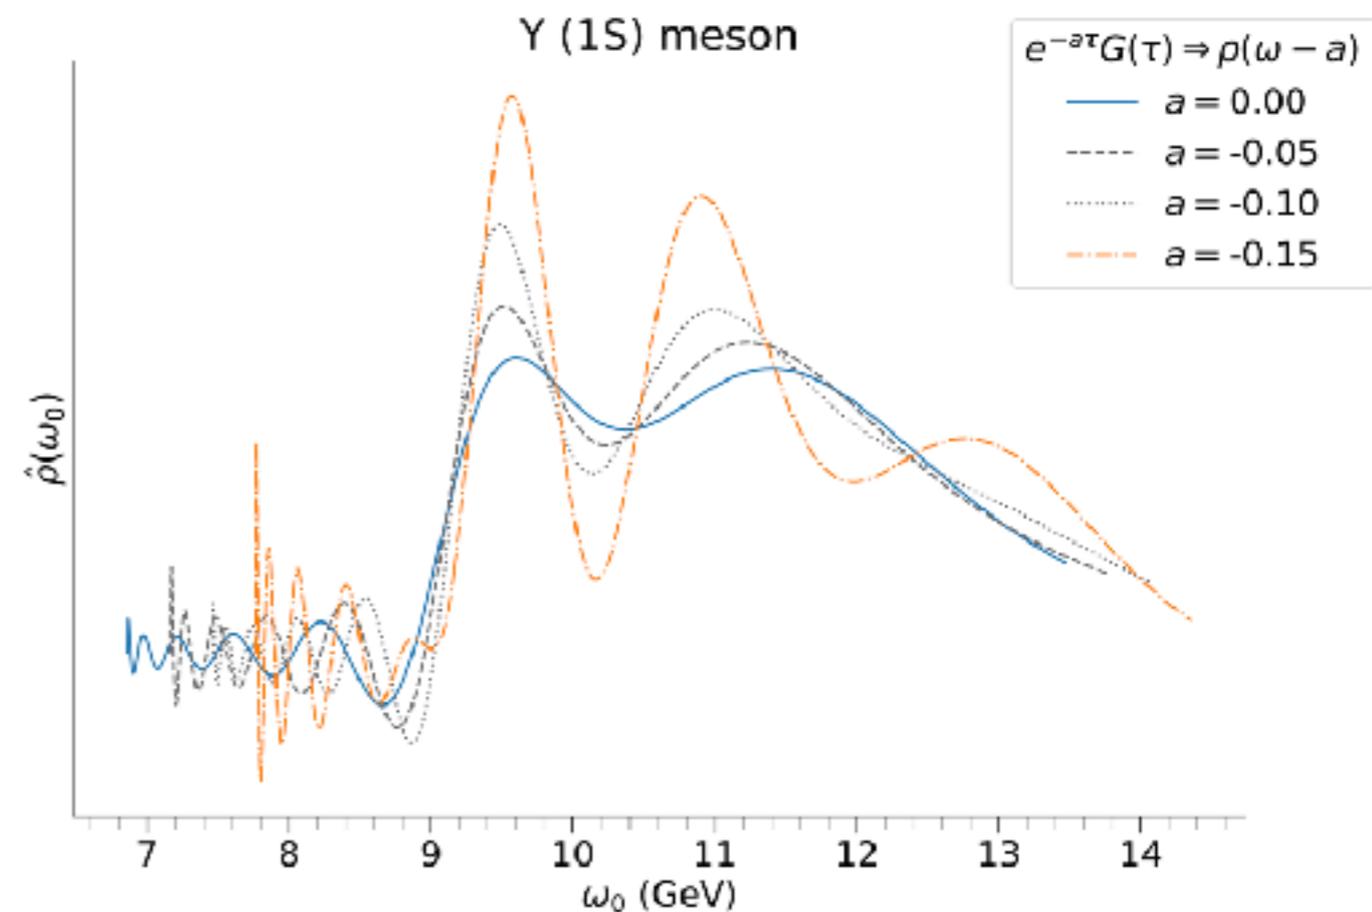

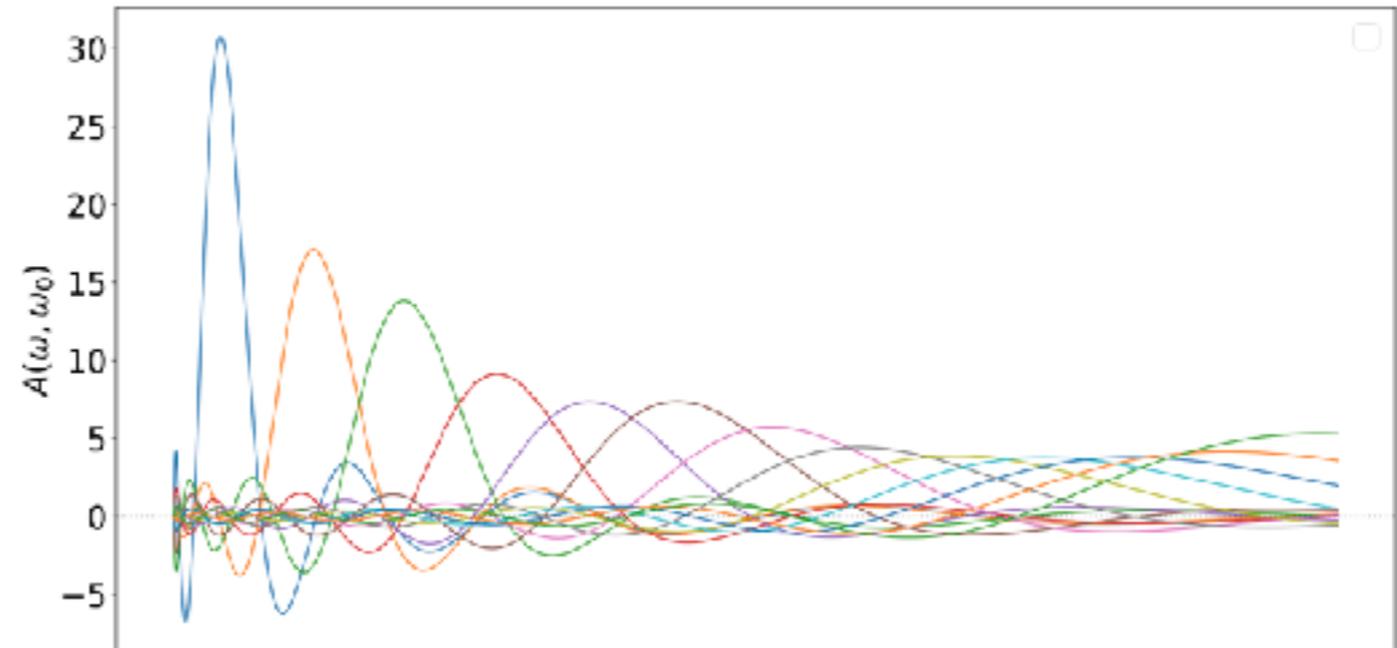

# Backus Gilbert Laplace Shift

- Increased sensitivity near origin
- Shift spectral features towards origin using Laplace transform properties:

$$G(\tau) = \int \rho(\omega) e^{-\omega\tau}$$

$$e^{a\tau} G(\tau) = \int \rho(\omega - a) e^{-\omega\tau}$$

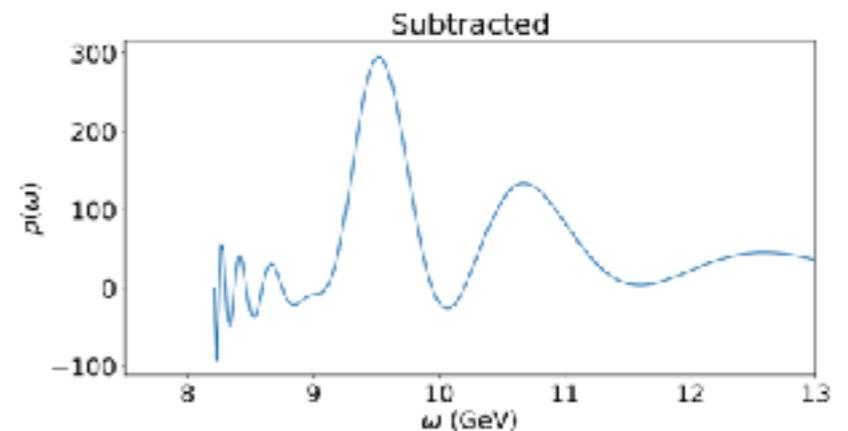

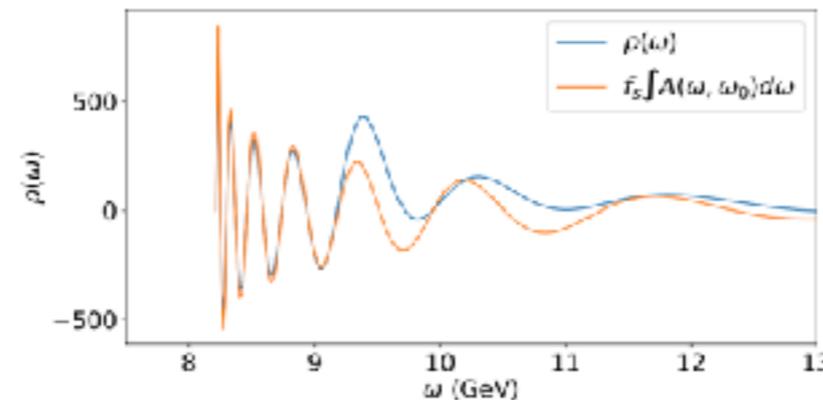

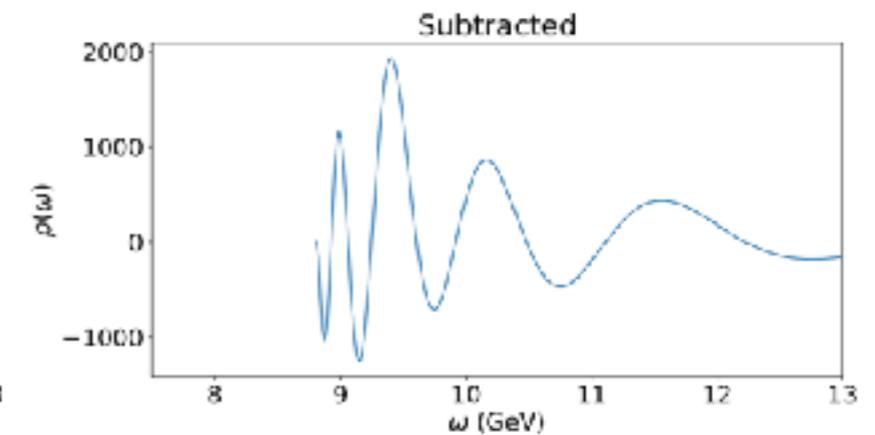

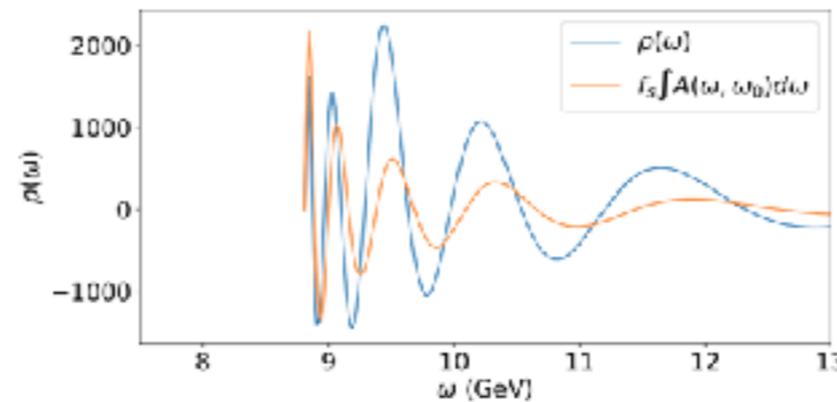

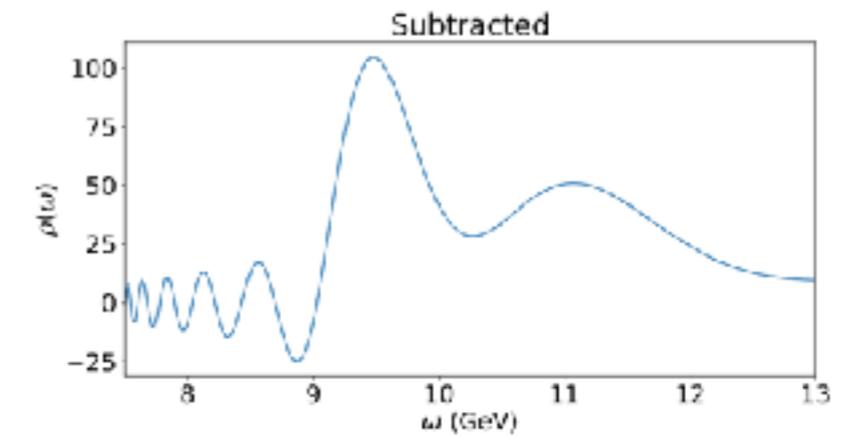

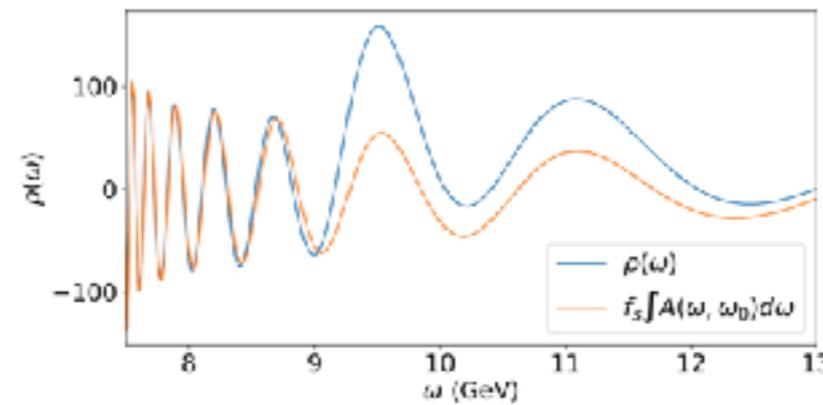

# Backus Gilbert Noise Subtraction

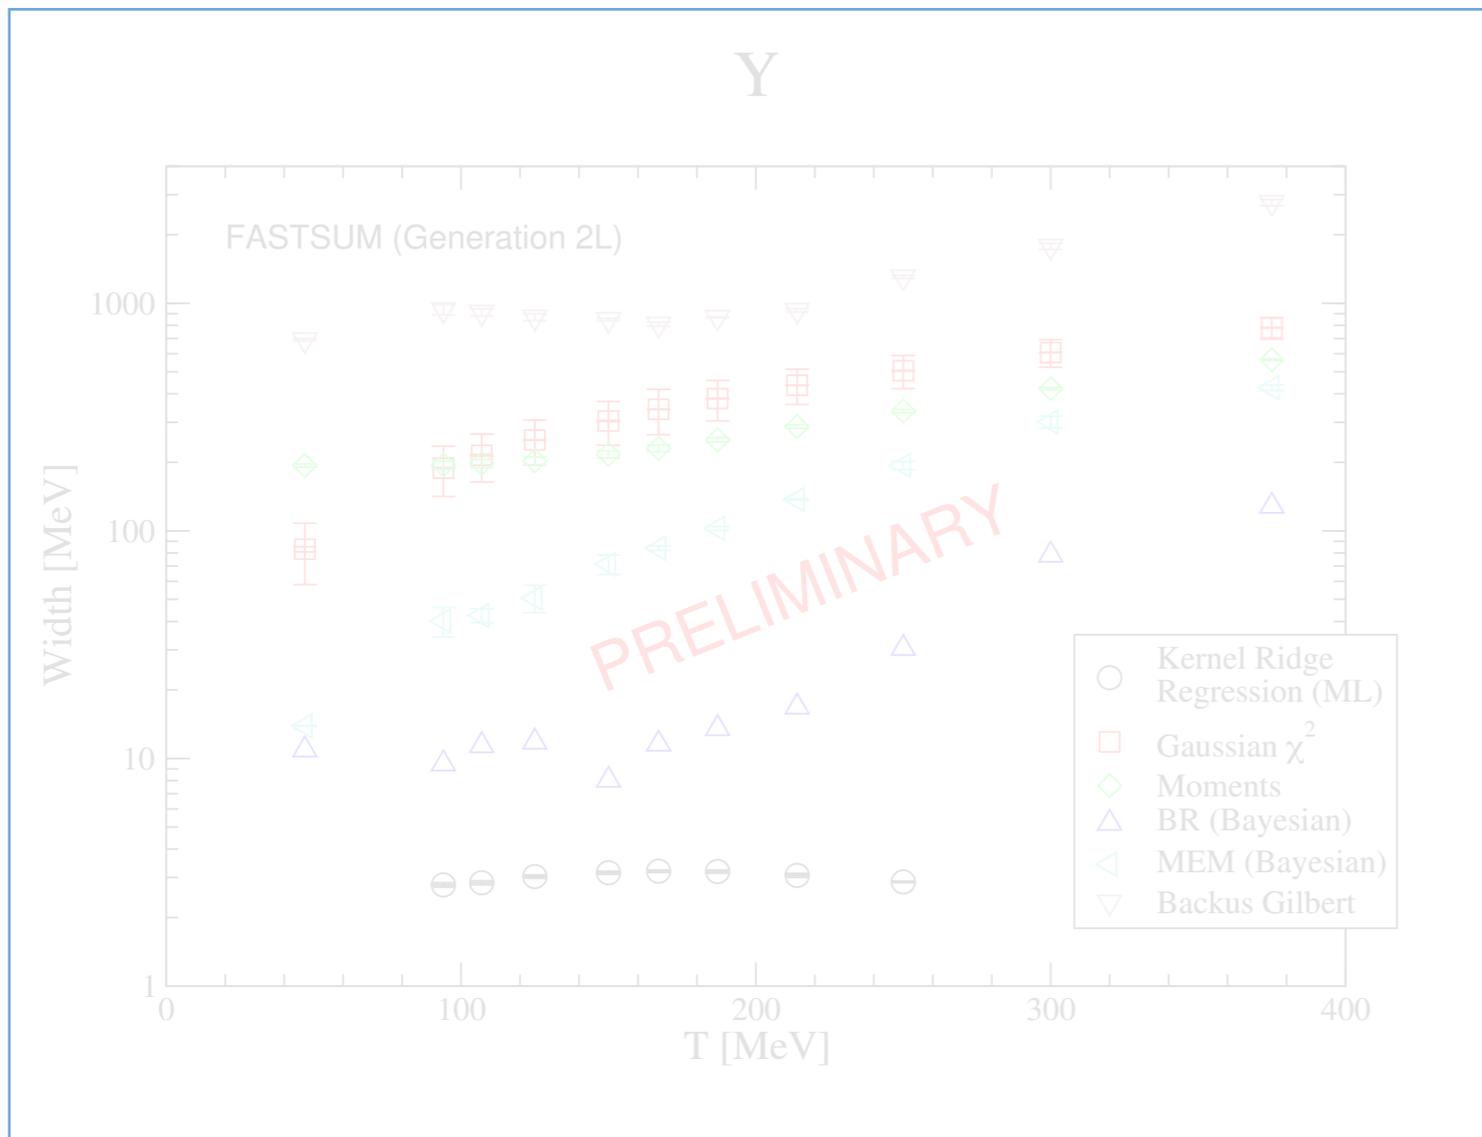

Can approximate noise/systematics by subtracting

$$\int A(\omega, \omega_0) d\omega \sim \text{BG spectrum of constant}$$

from BG spectrum
