Parameter inference/optimisation

Cosmological model $\mathcal{M}$

Parameters $\boldsymbol{\theta}$

For instance:

Standard LCDM

$\boldsymbol{\theta} = (\omega_b, \omega_{cdm}, H_0, \tau, A_s, n_s)$

or

LCDM + Neff

$\boldsymbol{\theta} = (\omega_b, \omega_{cdm}, H_0, \tau, A_s, n_s, N_{eff})$

etc.

Parameter inference/optimisation

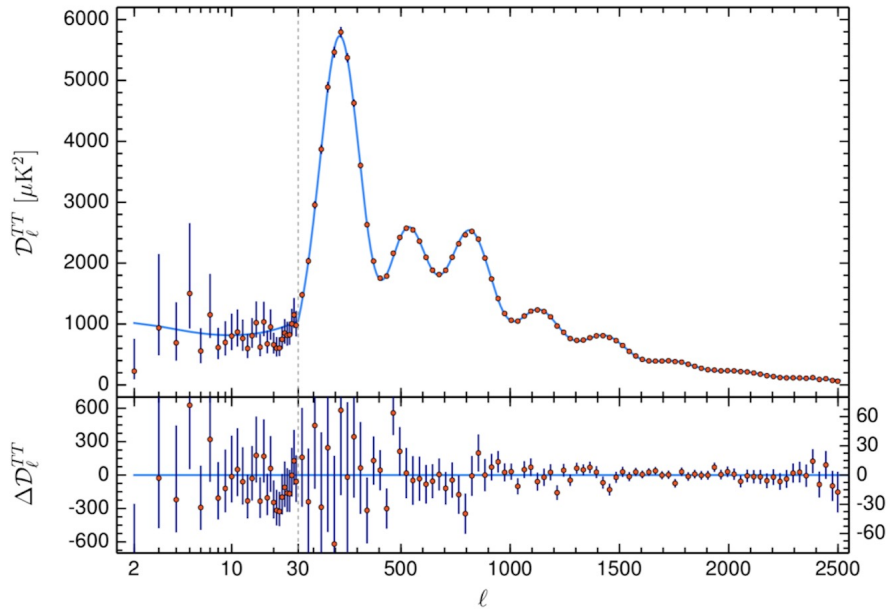
Cosmological model $\mathcal{M}$

Parameters $\boldsymbol{\theta}$

Boltzmann code
(CAMB/Class)

Theoretical prediction

(CMB angular power spectra)



Parameter inference/optimisation

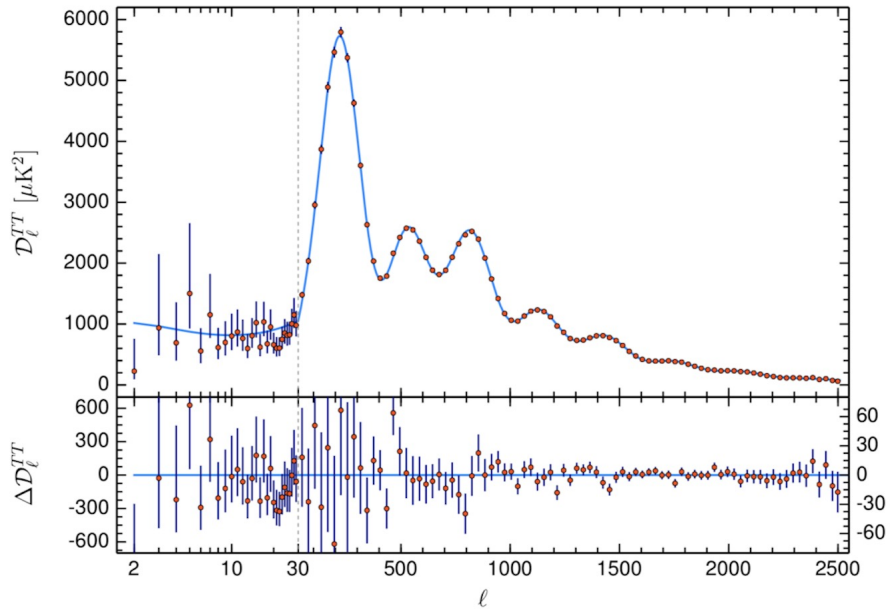
Cosmological model $\mathcal{M}$

Parameters $\boldsymbol{\theta}$

Boltzmann code
(CAMB/Class)

Theoretical prediction

(CMB angular power spectra)



Data $\mathcal{D}$

Likelihood

$\mathcal{L}(\mathcal{D}\,|\,\boldsymbol{\theta}, \mathcal{M})$

Probability of the data given the model and specific values of the parameters

For uncorrelated Gaussian measurements:

$$-2\ln\mathcal{L} = \chi^2 = \sum_i \left(\frac{x_{\mathrm{th}}^{(i)} - x_{\mathrm{d}}^{(i)}}{\sigma^{(i)}} \right)^2$$

theory data

error

Parameter inference/optimisation

Cosmological model $\mathcal{M}$

Parameters $\boldsymbol{\theta}$

Boltzmann code (CAMB/Class)

Theoretical prediction

(CMB angular power spectra)

Data $\mathcal{D}$

Likelihood

$\mathcal{L}(\mathcal{D}|\boldsymbol{\theta}, \mathcal{M})$

Prior $\pi(\boldsymbol{\theta}|\mathcal{M})$

Posterior probability

$\mathcal{P}(\boldsymbol{\theta}|\mathcal{D}, \mathcal{M})$

Bayes' Theorem

$$P(B|A) = \frac{P(A|B) \cdot P(B)}{P(A)}$$

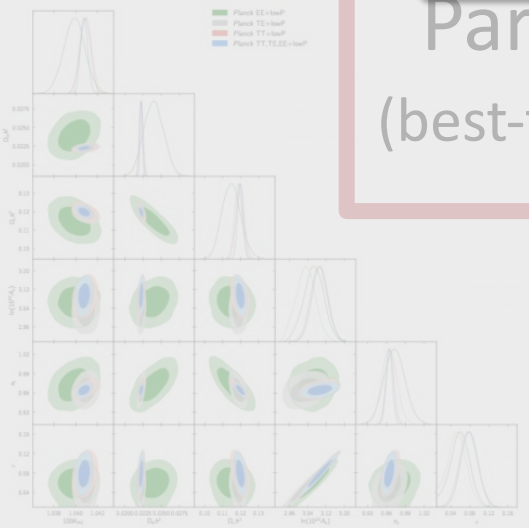
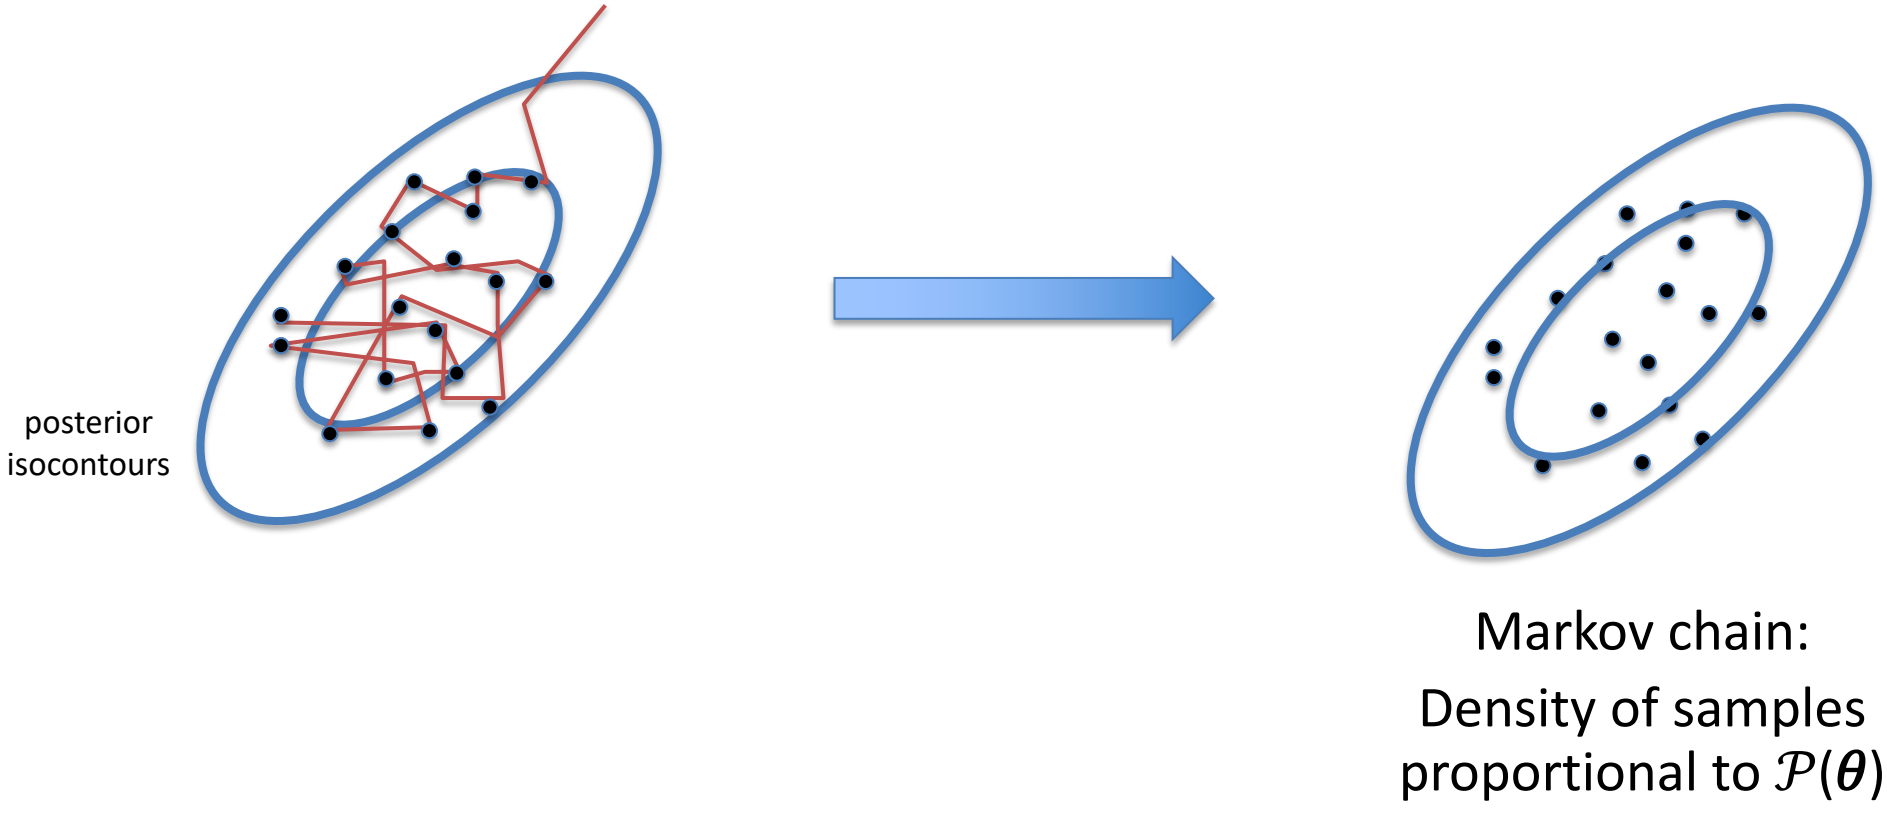
Can we trust these?

approximations, systematics (theoretical and experimental), modelling vs. first principles, propagation of uncertainties…



The usual approach: Markov chain Monte Carlo

- Basic idea: random walk in parameter space that explores $\mathcal{P}(\boldsymbol{\theta})$



The usual approach: Markov chain Monte Carlo

Metropolis-Hastings algorithm:

[Metropolis et al. (1953)]

1. Start at point $\boldsymbol{\theta}$ in parameter space
2. Save $\boldsymbol{\theta}$ to Markov chain
3. Propose a step to a new point $\boldsymbol{\theta}'$
4. Decide whether to accept the proposal and take the step:

   If $\mathcal{P}(\boldsymbol{\theta}') \geq \mathcal{P}(\boldsymbol{\theta})$, accept the proposal

   If $\mathcal{P}(\boldsymbol{\theta}') < \mathcal{P}(\boldsymbol{\theta})$, accept the proposal with a probability $p = \mathcal{P}(\boldsymbol{\theta}')/\mathcal{P}(\boldsymbol{\theta})$, otherwise reject
5. If step was accepted set $\boldsymbol{\theta}' = \boldsymbol{\theta}$
6. Go to 2.

http://chi-feng.github.io/mcmc-demo/app.html?algorithm=RandomWalkMH&target=standard

[Feng et al., Github]

Pros and cons of MCMC

+ easily implemented
+ easily parallelisable
+ essentially zero overhead
+ mild scaling of number of required samples with dimension N of parameter space (power law $\sim N^{\alpha}$ rather than exponential)
+ works great for near-Gaussian posteriors (most of cosmology)

o not very precise at finding the maximum
o typically requires $\mathcal{O}(10^4)$ function evaluations for N = $\mathcal{O}(10)$

– struggles with complicated (multi-modal, non-Gaussian, non-linearly correlated, etc.) posteriors
– not very smart: most of the information is ignored!

Bayesian optimisation

Step 1: Regression

Guess the shape of the function based on known function values (“data”)

Step 2: Selection

Decide at which point to evaluate the next function value

Goal: find global maximum of function

(and learn general shape in the process)

Bayesian optimisation

Step 1: Regression

Gaussian Process Regression

Guess the shape of the function based on known function values ("data")

Step 2: Selection

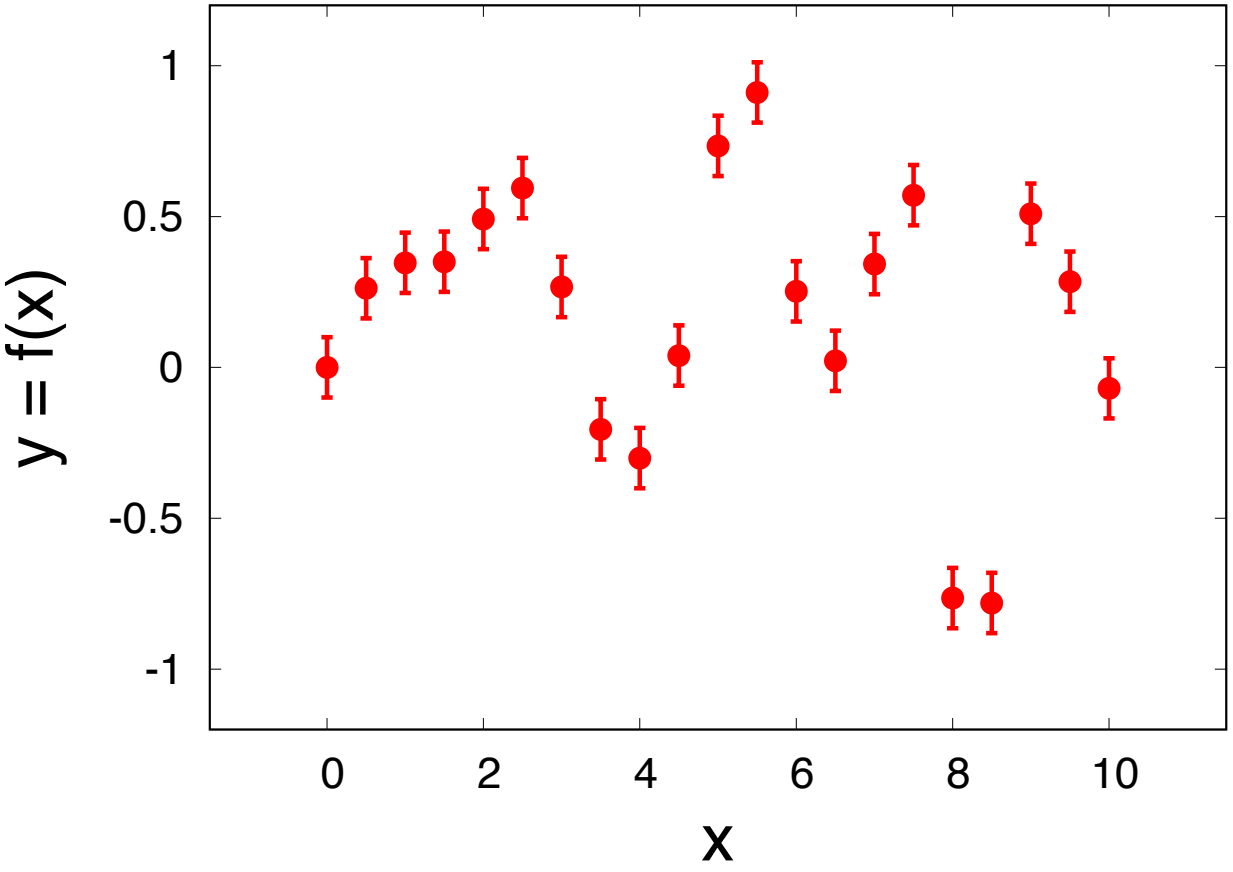
Acquisition function: Expected Improvement

Decide at which point to evaluate the next function value

Goal: find global maximum of function

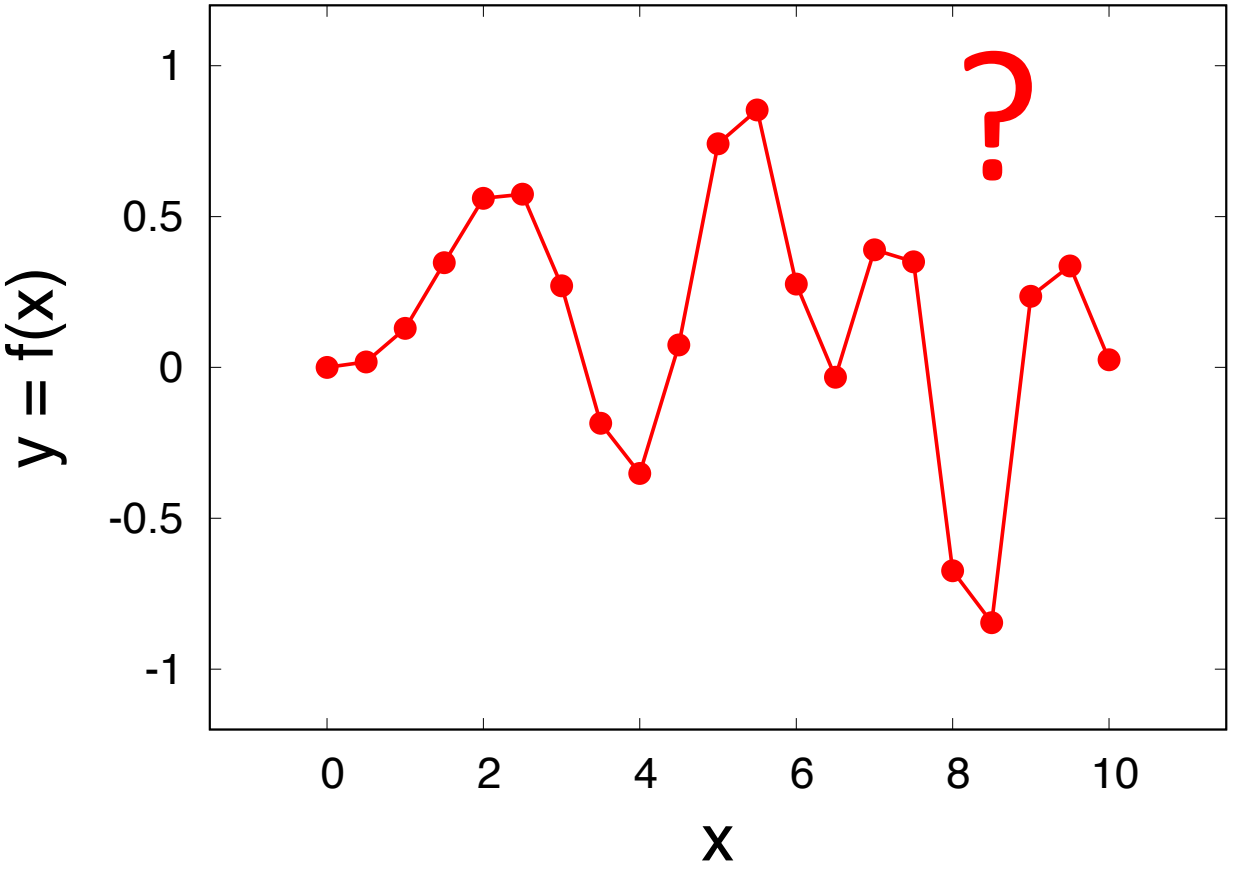
(and learn general shape in the process)

Gaussian Process Regression (GPR)



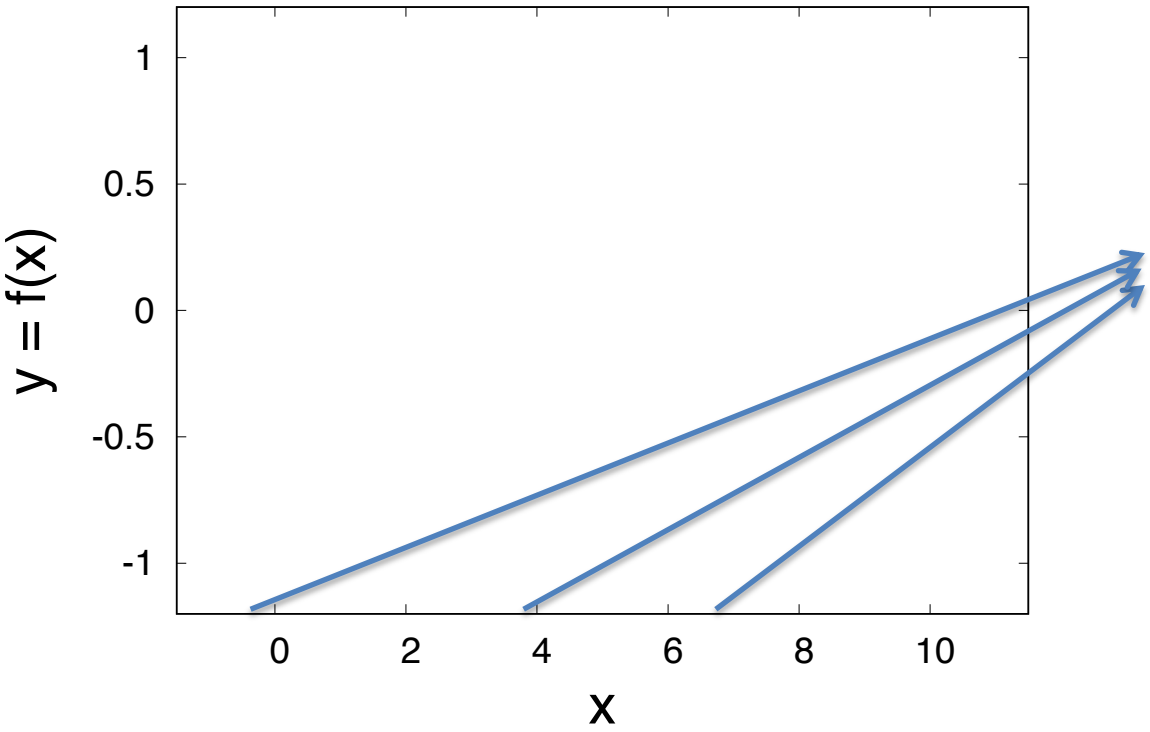
Data: (x_i, y_i) Covariance of the data: Σ_{ij}

Gaussian Process Regression (GPR)

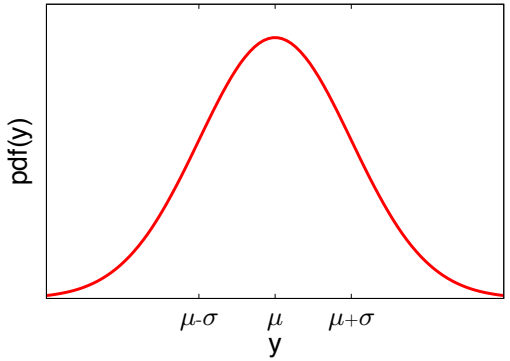


Data: (x_i, y_i)

Gaussian Process



draw a sample from



- Imagine for each x, f(x) is a random Gaussian variate drawn from $\mathcal{N}(\mu, \sigma^2)$

mean variance

Gaussian Process

- Gaussian process is specified by

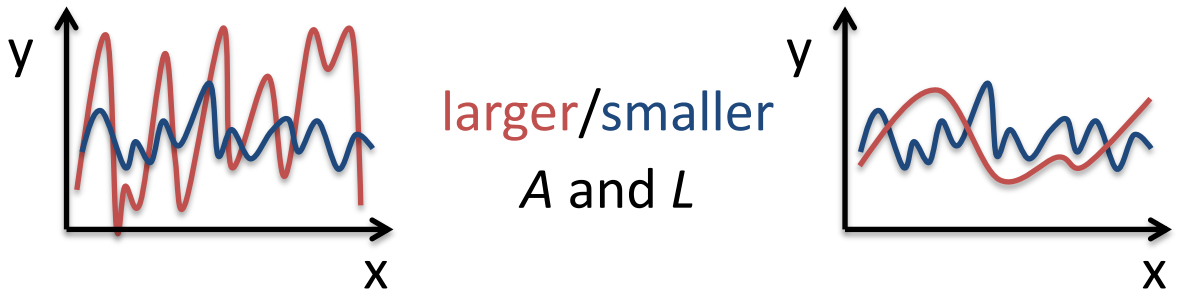
$$\mathcal{N}(\mu(x), K(x, x'))$$

covariance function

- Example covariance function:

$$K(x, x') = A \exp\left[-(x - x')^2 / L\right]$$

hyperparameters prior width correlation length



Gaussian Process Regression (GPR)

- Take function space generated by Gaussian process GP as *prior probability distribution* for f
- Impose data (x_i,y_i) as condition on GP
- $GP|(x_i,y_i)$ is the *posterior probability distribution* for f (this is still an infinite space of functions, but one can now evaluate, e.g., expectation value and covariance)

Gaussian Process Regression

Input

Data: (x_i, y_i)

Covariance of the data: Σ_{ij}

Covariance function: $K(x,x')$

} hyperparameters: h

Test values: x_i^*

straightforward
linear algebra

Output

Target means: $\bar{f}(x_i^*)$

Covariance of the targets: Σ_{ij}^*

Marginal likelihood: $E(h,\underline{y}|\underline{x})$

probability of the model given the data

Gaussian Process Regression

Input

Data: (x_i, y_i)

Covariance of the data: Σ_{ij}

Covariance function: $K(x,x')$ hyperparameters: h

Test values: x_i^*

straightforward linear algebra

Target means: $f(x_i^*)$

Output

Covariance of the targets: Σ_{ij}^*

Marginal likelihood: $E(h, \underline{y} | \underline{x})$

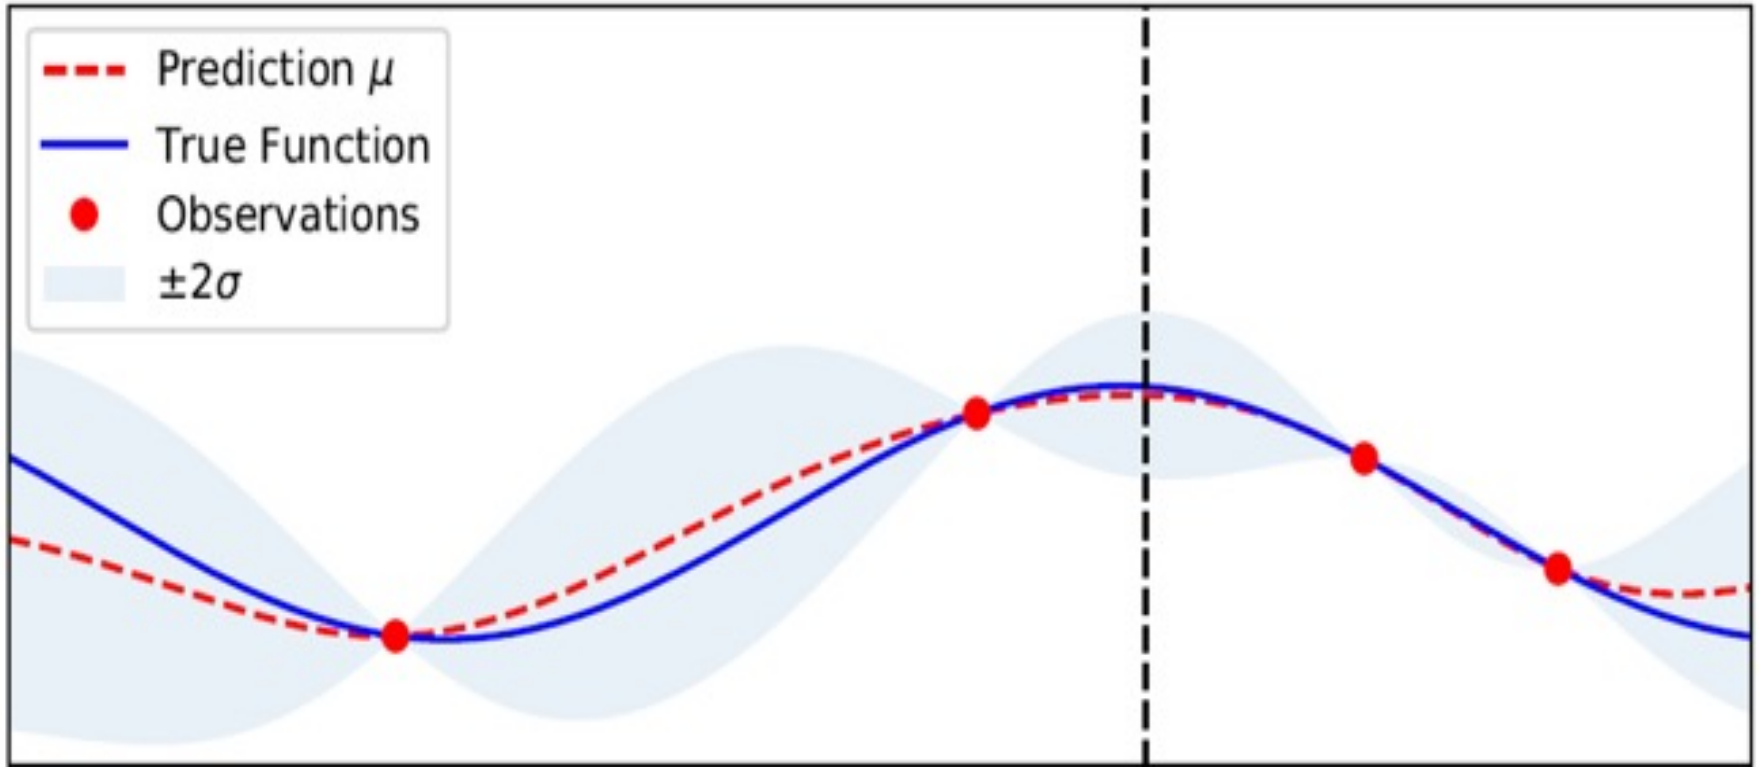
probability of the model given the data

Maximise marginal likelihood as function of hyperparameters

=

Let the data decide on the most appropriate Gaussian process!

Gaussian Process Regression



Where to draw the next sample?

Bayesian optimisation

Bayesian optimisation

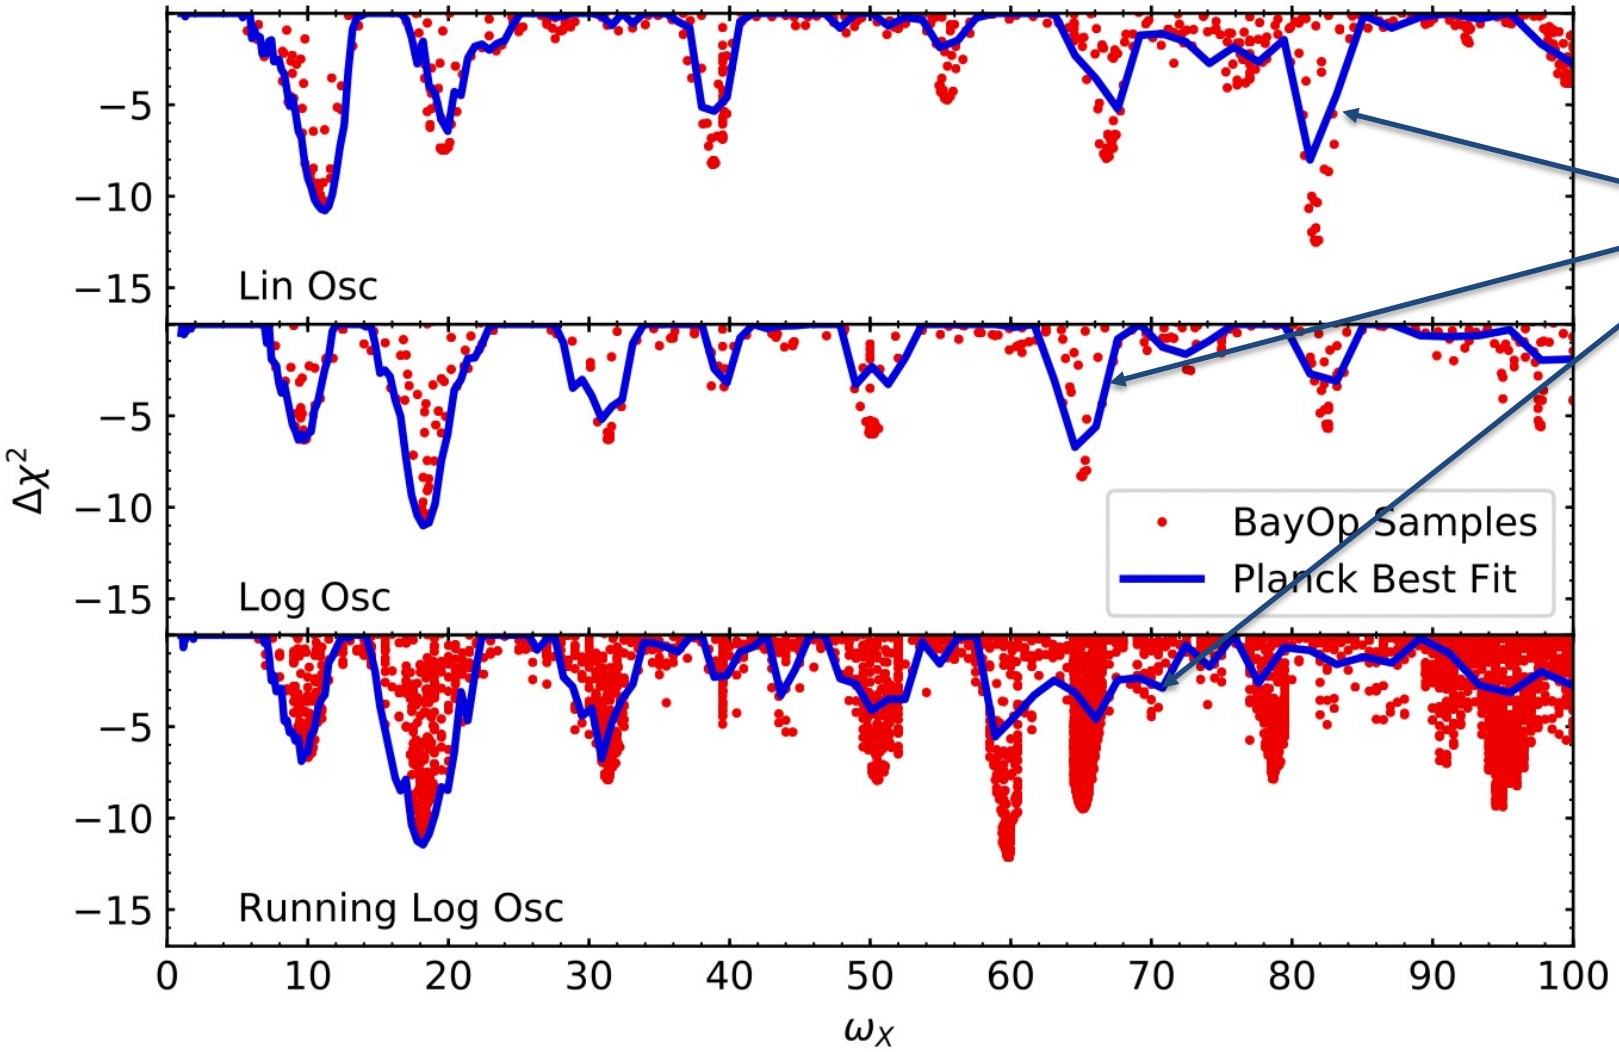
An example application: inflation models with modulated primordial power spectra



[*Planck* inflation 2018]

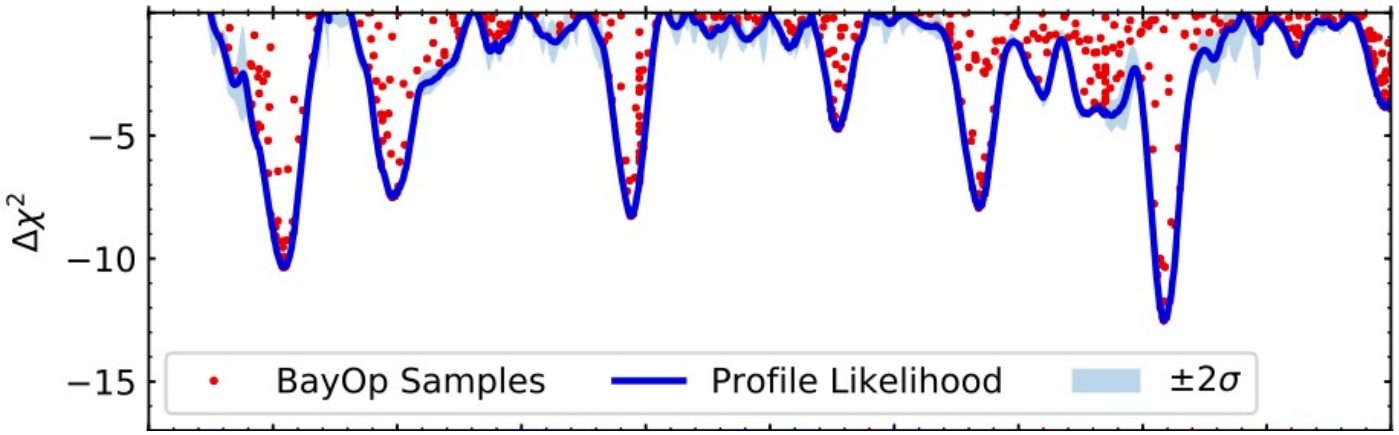
using nested sampling, $O(10^5)$ samples

red dots: our results with BO

- Two orders of magnitude fewer function evaluations
- Much better at finding global and local extrema

[JH & Wons, 2021]

BayOp – not only good for optimisation



1700 samples
8 frequency bins

… it also learns the global shape of the function

[JH & Wons, 2021]

Pros and cons of Bayesian Optimisation

+ high efficiency
+ excellent at finding global maximum
+ very good at determining overall shape, profiles of functions
+ works even for very nasty (non-Gaussian, multimodal, etc.) functions
+ does not require user input or fine-tuning of settings to work
− may struggle with higher-dimensional problems ($D \gtrsim 10$)
− non-trivial computational overhead (CPU time, memory)

Bayesian optimisation for parameter inference

- Learn shape of posterior probability density
- Replace (potentially expensive) calculation of theoretical prediction and likelihood evaluation with (cheap!) GPR emulation
- Implemented in a Python package: GPry [El Gammal et al., 2022]

But this assumes we know the right model…

Model selection: Bayesian method

$$P(\mathcal{M}|\mathcal{D}) = \frac{P(\mathcal{D}|\mathcal{M}) \cdot P(\mathcal{M})}{P(\mathcal{D})}$$

Probability of model $\mathcal{M}$ given the data $\mathcal{D}$

Bayesian evidence

$$P(\mathcal{D}|\mathcal{M}) = \int \mathrm{d}\theta \, \mathcal{L}(\mathcal{D}|\theta, \mathcal{M}) \, \pi(\theta|\mathcal{M})$$

Comparing two models: Bayes factor B_{12}

$$B_{12} = \frac{P(\mathcal{D}|\mathcal{M}_1)}{P(\mathcal{D}|\mathcal{M}_2)}$$

"Model $\mathcal{M}_1$ is B_{12} times more probable than $\mathcal{M}_2$"

Model selection: Bayesian method

Bayesian evidence

$$P(\mathcal{D}|\mathcal{M}) = \int \mathrm{d}\theta\ \mathcal{L}(\mathcal{D}|\theta,\mathcal{M})\,\pi(\theta|\mathcal{M})$$

- Integral over entire parameter space
- Rewards models that make *risky* predictions and *get it right* over generic models that can *fit anything*
- Natural implementation of Occam's razor:

Numquam ponenda est pluralitas sine necessitate

Plurality must never be posited without necessity

Bayesian model selection

- Multi-dimensional integration is a challenging task
- Standard approach: Nested sampling algorithm

[Skilling 2004, Feroz et al. 2013, Handley et al. 2015]

- typically requires $\mathcal{O}(10^5\text{-}10^6)$ function evaluations for features models

This is even harder than parameter inference
Can Bayesian Optimisation help?

Evidence calculation with Bayesian optimisation

- Goal is to select next function value to be evaluated in such a way that it maximises the expected reduction in uncertainty of the integral
- Use a different acquisition function: Integrated Mean Square Prediction Error (IMSPE)

$$\mathrm{IMSPE}(\theta) = \int \mathrm{d}\theta' \, \sigma_{\widehat{\mathrm{GP}(\theta)}}(\theta')$$

GPR uncertainty

Pretend to take a sample at θ, then do a new GPR

Very convenient:
gives estimate of the uncertainty of the evidence integral

Evidence calculation with Bayesian optimisation

- Our code still in development…
- Code based largely on existing Python frameworks (BoTorch)

[Balandat et al. (2019)]

- Uses clever method for dealing with hyperparameters and acquisition function maximization (Sparse Axis-Aligned Subspace Bayesian Optimisation (SAASBO))

[Eriksson & Jankowiak (2021)]

- Sampling from hyperparameter space PDF instead of maximizing (overengineering? – but more Bayesian in spirit)

Conclusions

- Bayesian optimisation is a very efficient machine-learning technique for extremising unknown functions
- It can also be applied to cosmological parameter estimation and Bayesian model comparison
- Most useful for expensive-to-calculate likelihoods and complicated posterior distributions
- Paper and code for Bayesian evidence calculation out soon!
