The Dark Matter Connection: Theory and Experiment  
GGI, Arcetri, Florence      May 17th-21st 2010

# [1] the relevance of the local dark matter density

$$\rho_0 \equiv \rho_{dm}(R_0 \sim 8 \text{ kpc})$$

::  $\rho_0$  is a main astrophysical unknown for DM searches ::

key ingredient to compute DM signals and draw limits  
uncertainties on  $\rho_0$  are crucial in interpreting positive DM detections

## scattering at the detector

$$\frac{dR}{dE} \propto n_{dm} \int_{v_{min}}^{\infty} dv \frac{f(v)}{v} \propto \rho_0$$

signal: nuclei recoils

sensitive to  $\langle \rho_0 \rangle_{mpc}$

## capture in Sun/Earth

$$\frac{dN_{dm}}{dt} = C - 2\Gamma_{ann}$$

$$C \propto n_{dm} \int_0^{v_{max}} dv \frac{f(v)}{v} \propto \rho_0$$

signal:  $\nu$  from Sun/Earth

sensitive to  $\langle \rho_0 \rangle$

## halo annihilation/decay

$$\frac{d\phi}{dE} \propto \langle \sigma_{ann} v \rangle n_{dm}^k \propto \rho_0^k$$

signals:  $\gamma$ ,  $e^+$ ,  $\bar{p}$ ,  $\nu$

sensitive to  $\langle \rho_0 \rangle$

[not the largest unknown]

# [1] from dynamical observables to $\rho_0$

## Milky Way mass model

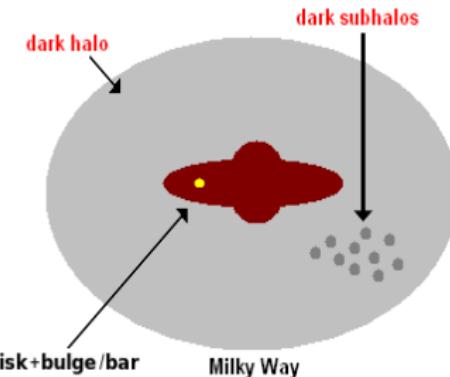

bulge(+bar)  $\lesssim 3$  kpc  $\rho_b(x, y, z)$   $x_b, y_b, z_b$

disk  $\lesssim 10$  kpc  $\rho_d(r, z)$   $\Sigma_d, r_d, z_d$

dark halo  $\lesssim 200$  kpc  $\rho_{dm}(x, y, z) \propto \rho_0$

+gas...

a model fixes  $M_i(R), \phi_i(R)$

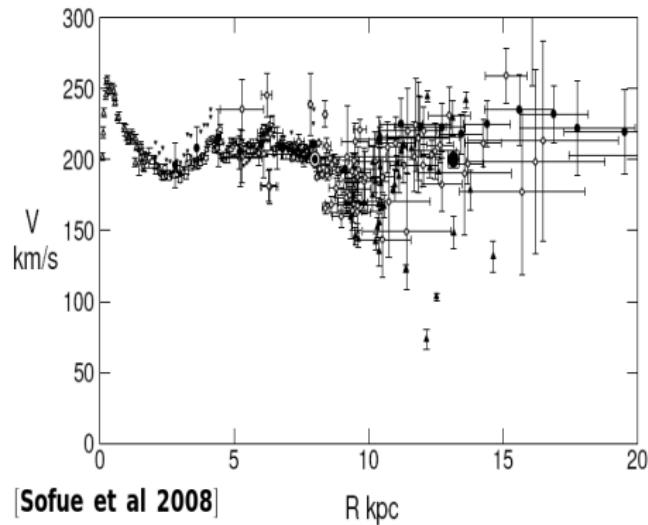

$$\sum_i \frac{d\phi}{dR}(R) \equiv \frac{G}{R^2} \sum_i M_i(< R) = \frac{v^2(R)}{R} \quad v_0 \equiv v(R_0)$$

spherical average local density

$$\bar{\rho}_0 \simeq \frac{1}{4\pi R_0^2} \left( \frac{1}{G} \frac{\partial (v^2 R)}{\partial R} \Big|_{R_0} - \frac{dM_d}{dR} \Big|_{R_0} \right)$$

# [1] from dynamical observables to $\rho_0$

observables

$$R_0, \quad A - B = v_0/R_0, \quad A + B = -v'_0 \\ [\text{fix } v_0, v'_0]$$

mass enclosed

$$M(< 50 \text{ kpc}) \quad M(< 100 \text{ kpc})$$

local surface density

$$\Sigma_{|z|<1.1 \text{ kpc}} \quad \Sigma_*$$

terminal velocities  $R < R_0$   
 $v(R) = v_T(l) + v_0 \sin(l)$

velocity dispersions  $R \gtrsim R_0$  (tracer populations)

Jeans (sph., steady)  $\frac{\partial(\nu\sigma_R^2)}{\partial R} + \frac{2\beta\sigma_R^2\nu}{R} = \nu \sum_i \frac{d\phi_i}{dR} = -\frac{\nu G}{R^2} \sum_i M_i(< R)$

$$\sigma_{los} \propto \sigma_R$$

microlensing

$$\tau_{LMC} \sim 10^{-7} \quad \tau_{bulge} \sim 10^{-6} \quad [\text{constrain } M_b]$$

# [1] from dynamical observables to $\rho_0$

**aim:** use observables to constrain mass model parameters

**selected references** (different models/observables)

Caldwell & Ostriker '81       $\rho_0 = 0.23 \pm \times 2 \text{ GeV/cm}^3$

Gates, Gyuk & Turner '95       $\rho_0 = 0.30_{-0.11}^{+0.12} \text{ GeV/cm}^3$

Moore et al '01       $\rho_0 \simeq 0.18 - 0.30 \text{ GeV/cm}^3$

Belli et al '02       $\rho_0 \simeq 0.18 - 0.71 \text{ GeV/cm}^3$  (isoth.)

Strigari & Trotta '09       $\Delta \rho_0 / \rho_0 = 20\%$  (projected; 2000 halo stars,  $v_{esc}$ )

Catena & Ullio '09       $\rho_0 \simeq 0.39 \pm 0.03 \text{ GeV/cm}^3$        $\Delta \rho_0 / \rho_0 = 7\% !!$

Salucci et al '10       $\rho_0 \simeq 0.43 \pm 0.21 \text{ GeV/cm}^3$

**usual assumptions:**  $\rho_{dm} = \rho_{dm}(r)$ ,  $\rho_{dm}$  from DM-only simulations

# [1] the role of baryons on dark matter halos

adiabatic contraction [Blumenthal et al 1986]

spherical mass distribution  $M_i(< R_i)$ : baryons + dark matter     $f_b \sim 0.17$   
baryons cool and contract slowly  $\rightarrow M_b(< R)$   
circular orbits +  $L = \text{const}$

$$R(M_b(< R) + M_{dm}(< R)) = R_i M_i(< R_i) = R_i M_{dm}(< R)/(1 - f_b)$$

$$\rho_{dm} \propto R^{-2} \frac{dM_{dm}}{dR}$$

final DM profile is significantly contracted

[+ Gnedin et al 2004, Gustafsson et al 2006]

## halo shape

DM-only halos are prolate

+ baryons: more oblate halos (still triaxial)

in any case,  $\rho_{dm} \neq \rho_{dm}(r)$

### aim

address systematics on  $\rho_0$  in light of recent N-body+hydro simulations  
a realistic pdf on  $\rho_0$  is needed if we are to convincingly identify WIMPs

## [2] our numerical framework

difficult to obtain a MW-like galaxy at  $z = 0$  with simulations  
usually large bulges and small disks result ( $L$  problem)

recent sucessful attempt: Agertz, Teyssier & Moore 2010  
dark matter + gas + stars

### cosmological setup

WMAP 5yr cosmology  
select DM-only halo  
 $M_{vir} \sim 10^{12} M_\odot$     $R_{vir} \sim 205$  kpc  
no major merger for  $z < 1$

### baryonic features

star formation (Schmidt law;  $\epsilon_{ff}$ ,  $n_0$ )  
$$\dot{\rho}_g = -\epsilon_{ff} \frac{\rho_g}{t_{ff}}$$
 stellar feedback (SNII, SNIa, wind)

### numerical features

$m_{DM} = 2.5 \times 10^6 M_\odot$   
 $\Delta x = 340$  pc

### main result

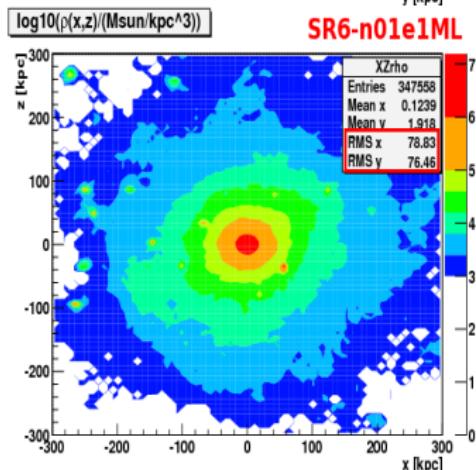

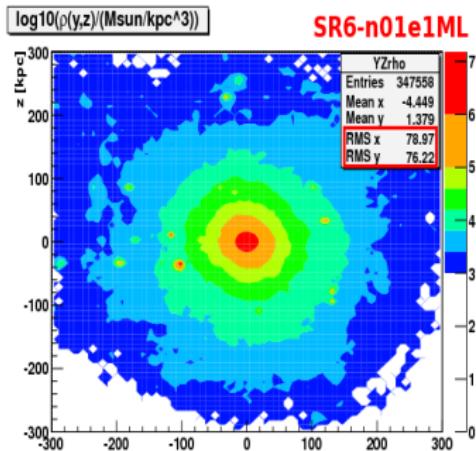

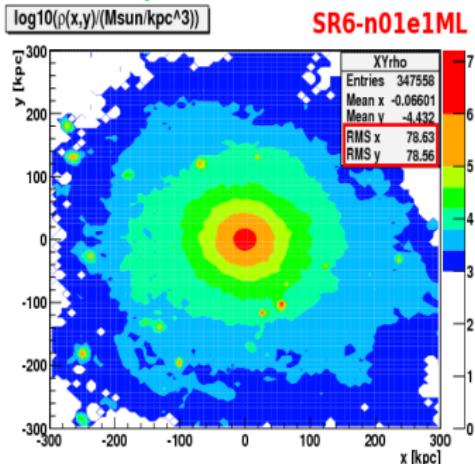

MW-like galaxy with  $v_c \sim const$ ,    $B/D \sim 0.25$ ,    $r_d \sim 4 - 5$  kpc

## [2] our numerical framework

Run	$\epsilon_{\text{ff}}$	Feedback	Star formation threshold, $n_0$

SR6-n1e2	6.4	2.4	4.3	2.5	0.18	0.67	0.40	1804
SR6-n1e5	6.0	2.1	5.2	2.7	0.16	0.87	0.46	1643

to bracket uncertainties we consider: DM-only, SR6-n01e1ML, SR6-n01e5ML

### [3] halo shape: a first look

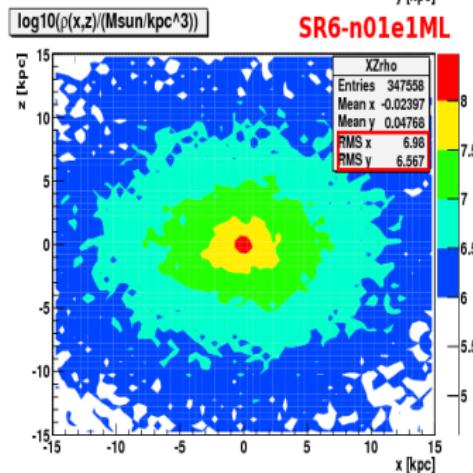

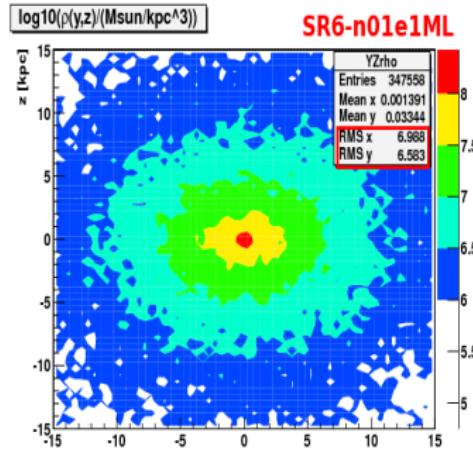

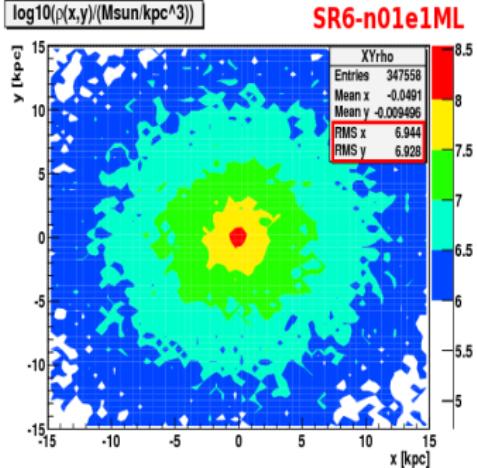

profiles of dark matter density

SR6-n01e1ML :: MW-like

$$10^7 M_{\odot}/kpc^3 \sim 0.38 \text{ GeV/cm}^3$$

### [3] halo shape: a first look

profiles of dark matter density

SR6-n01e1ML :: MW-like

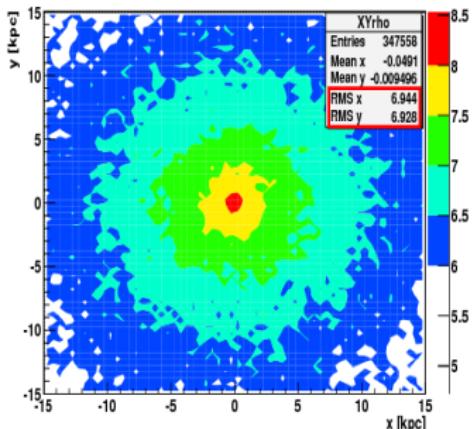

approximately axisymmetric halo

$$10^7 M_{\odot}/kpc^3 \sim 0.38 \text{ GeV/cm}^3$$

### [3] halo shape: a first look

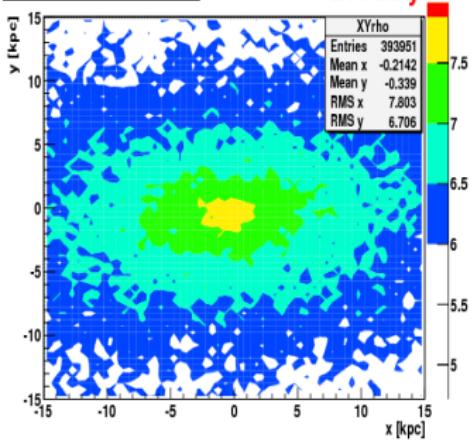

$\log_{10}(\rho(x,y)/(M_{\odot}/kpc^3))$

SR6-n01e1ML

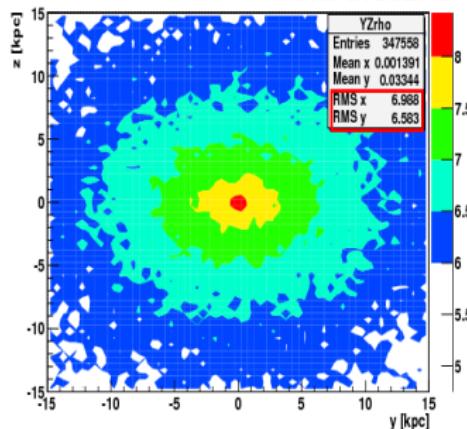

$\log_{10}(\rho(x,y)/(M_{\odot}/kpc^3))$

DM only

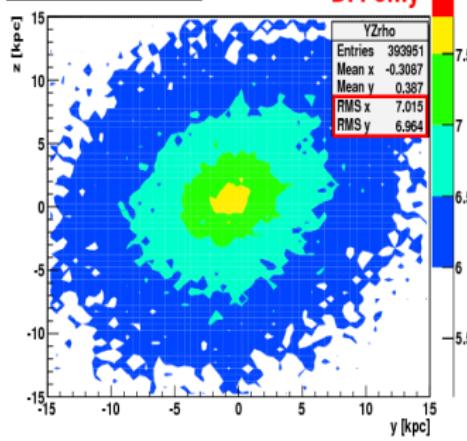

$\log_{10}(\rho(y,z)/(M_{\odot}/kpc^3))$

SR6-n01e1ML

$\log_{10}(\rho(y,z)/(M_{\odot}/kpc^3))$

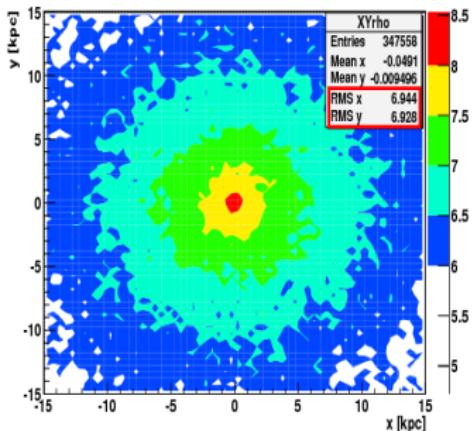

DM only

### [3] halo shape: a first look

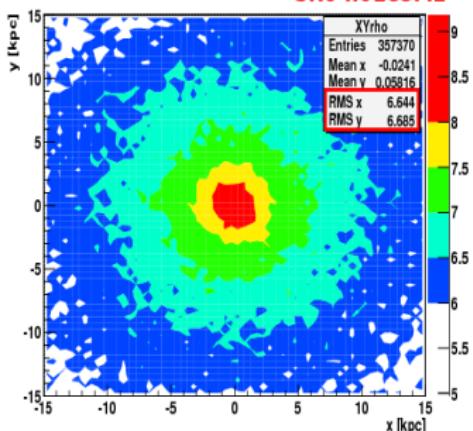

$\log_{10}(\rho(x,y)/(M_{\odot}/kpc^3))$

SR6-n01e1ML

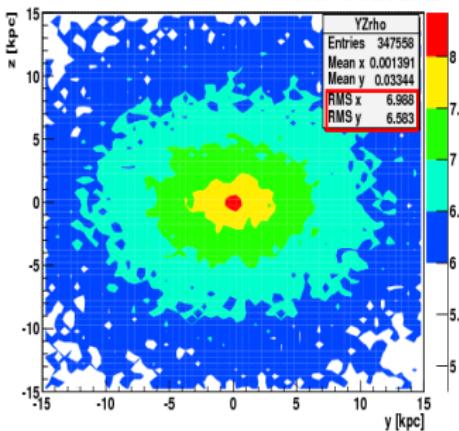

$\log_{10}(\rho(x,y)/(M_{\odot}/kpc^3))$

SR6-n01e5ML

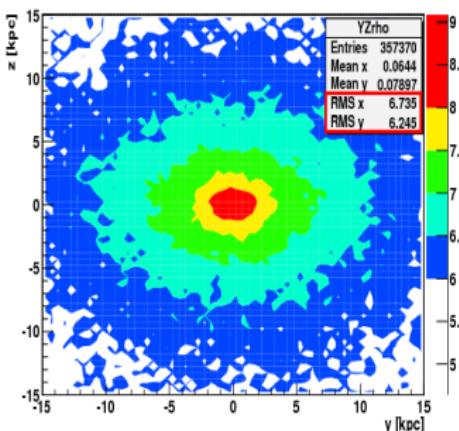

$\log_{10}(\rho(y,z)/(M_{\odot}/kpc^3))$

SR6-n01e1ML

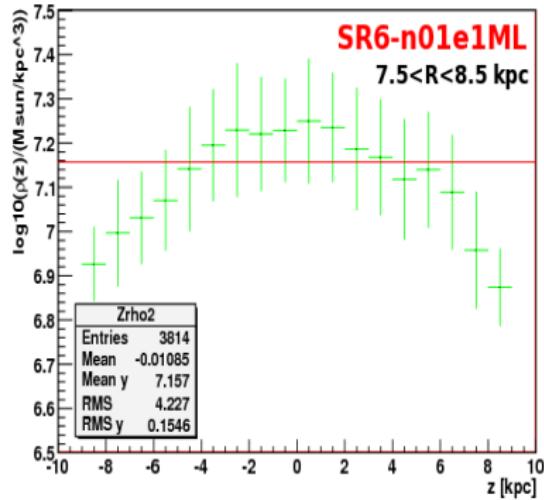

$\log_{10}(\rho(y,z)/(M_{\odot}/kpc^3))$

SR6-n01e5ML

### [3] halo shape: a first look

local spherical shell:  $7.5 < R < 8.5 \text{ kpc}$

DM overdensity towards  $z \sim 0$   
(i.e. stellar disk)

bottomline

baryons make DM halos rounder (but still non-spherical) and  
flattened along the stellar disk

### [3] halo shape: getting more quantitative

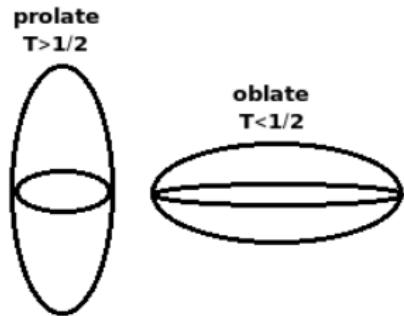

#### inertia calculations

for a set of  $N_p$  particles,  $J_{ij} = \frac{\sum_{k=1}^{N_p} m_k x_{i,k} x_{j,k}}{\sum_{k=1}^{N_p} m_k}$

principle axes: eigenvectors  $\vec{j}_a$  (major),  $\vec{j}_b$  (intermediate),  $\vec{j}_c$  (minor)

axis ratios:  $b/a = \sqrt{J_b/J_a}$ ,  $c/a = \sqrt{J_c/J_a}$

triaxiality:  $T = \frac{1-b^2/a^2}{1-c^2/a^2}$

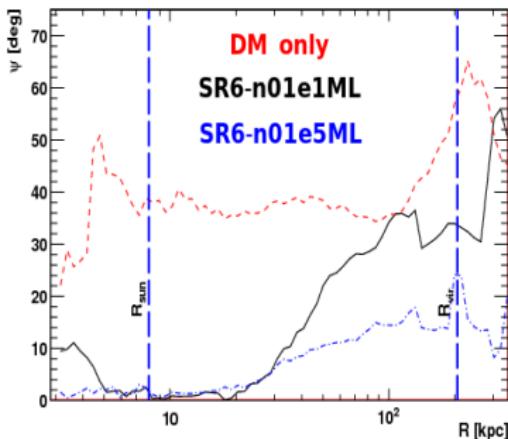

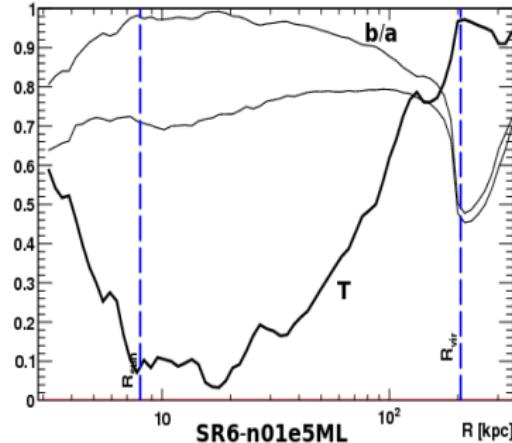

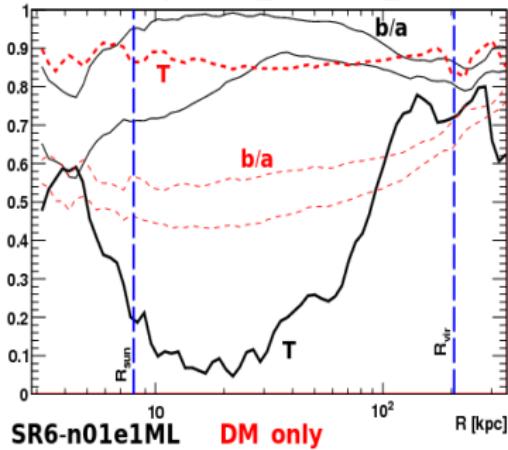

iterative procedure [a la Katz et al '91]

$$r < R \rightarrow b/a, c/a, \vec{j}_{a,b,c} \rightarrow q = \sqrt{x^2 + \frac{y^2}{(b/a)^2} + \frac{z^2}{(c/a)^2}} < R \rightarrow \dots$$

convergence criterium: 0.5% change in  $b/a, c/a$

### [3] halo shape: getting more quantitative

inclusion of baryons

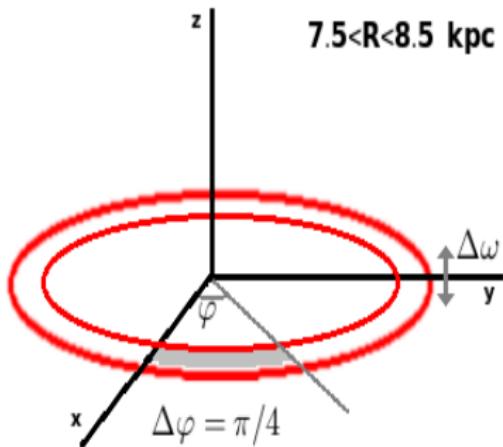

prolate  $\rightarrow$  oblate halo shape  
 flattening aligned with stellar disk for  
 $R \lesssim 20$  kpc

### [3] halo shape: consequences for $\rho_0$

- / many studies assume a spherical halo [e.g. Catena & Ullio, Strigari & Trotta]
- / data then constrains the spherical average local density  $\bar{\rho}_0$ :

$$\bar{\rho}_0 \simeq \frac{1}{4\pi R_0^2} \left( \frac{1}{G} \left. \frac{\partial(v^2 R)}{\partial R} \right|_{R_0} - \left. \frac{dM_d}{dR} \right|_{R_0} \right)$$

- / model triaxial halo is tricky ( $b/a$ ,  $c/a$  not known nor constant)
- / to estimate **systematic uncertainty** compare  $\bar{\rho}_0 \leftrightarrow \rho_0$  in simulations

strategy

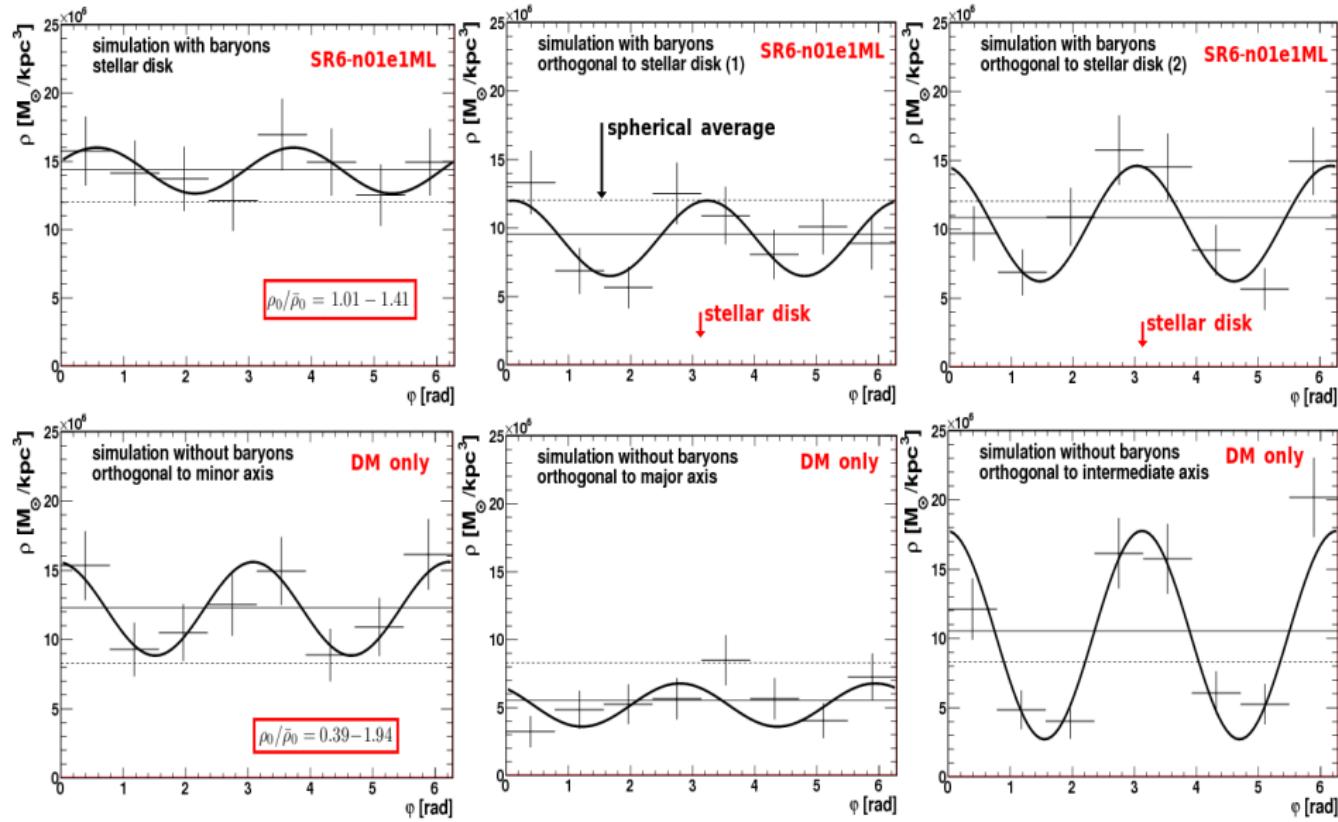

spherical shell  $7.5 < R < 8.5$  kpc

select particles in 3 orthogonal rings

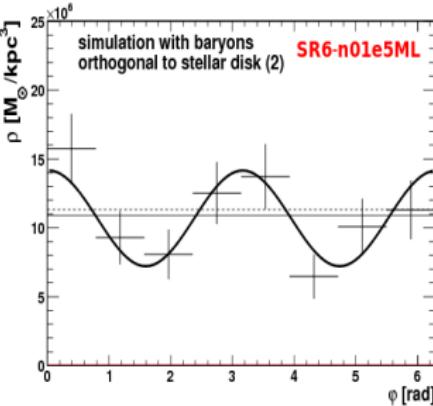

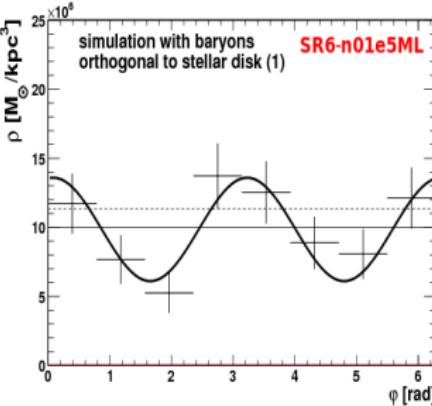

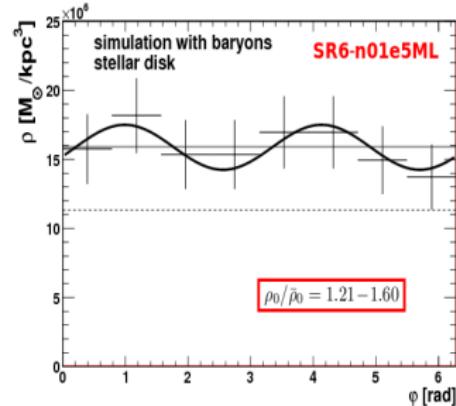

divide rings into 8 portions  $\Delta\varphi = \pi/4$

evaluate  $\rho$  along the ring,  $\rho(\varphi)$

### [3] halo shape: consequences for $\rho_0$

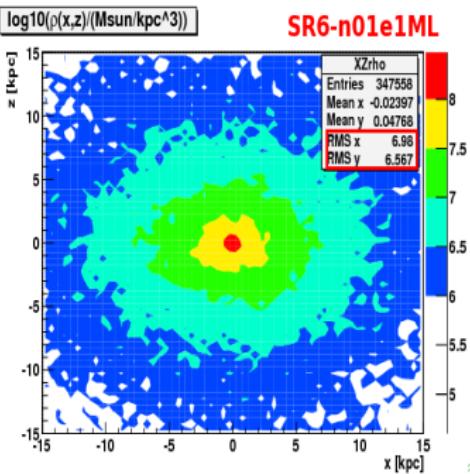

### [3] halo shape: consequences for $\rho_0$

SR6-n01e1ML	1.01–1.41
SR6-n01e5ML	1.21–1.60
DM only	0.39–1.94

- /  $\rho(\varphi) > \bar{\rho}_0$  because halo is flattened
- / halo-to-halo scatter can change normalisation

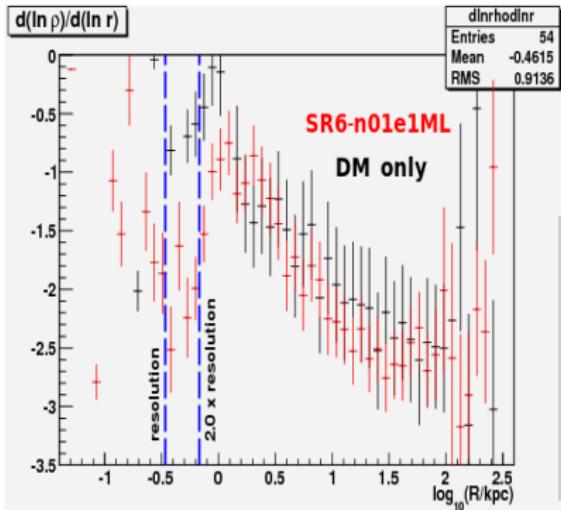

## [4] halo profile

DM-only simulations find NFW|Einasto profiles

$$\frac{\partial \ln \rho}{\partial \ln R} \rightarrow -1 | 0 \text{ as } R \rightarrow 0$$

baryons expected to contract DM profile

$\frac{\partial \ln \rho}{\partial \ln R} < -1$  for  $R < 1$  kpc

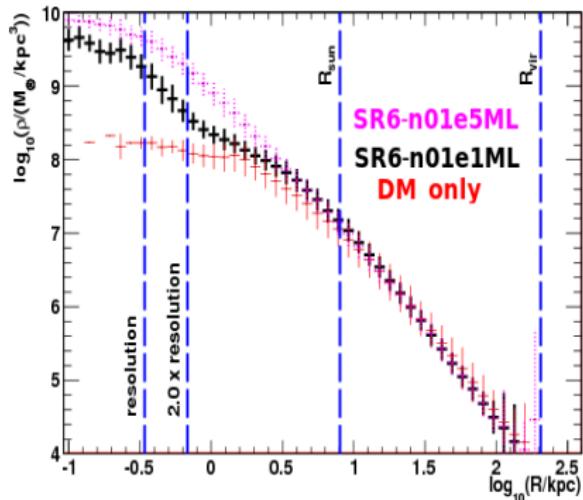

but: no convergence;  $R > 2\Delta x$

teaser

if  $\rho_{dm} \propto R^{-2}$ , extrapolation to pc (why not?)  
yields extreme annihilation signals

e.g. for Fermi-LAT GC  $\gamma$ ,  
 $\langle \sigma_{ann} v \rangle \lesssim 10^{-28} \text{ cm}^3/\text{s} @ m_{dm} = 100 \text{ GeV}$

## [4] halo profile

	NFW fit $1 < R/\text{kpc} < 100$		power law fit	
	$\log_{10}(\rho_s / (\text{M}_\odot / \text{kpc}^3))$	$R_s/\text{kpc}$	$0.340 < R/\text{kpc} < 1$	$0.680 < R/\text{kpc} < 10^{0.1}$
SR6-n01e1ML	7.57 (7.61)	9.48 (8.43)	1.97 (1.58)	1.14 (1.16)
DM only	7.08 (6.97)	15.59 (15.42)	0.46 (0.68)	0.24 (0.36)
SR6-n01e5ML	8.13 (7.76)	5.58 (7.38)	1.54 (1.59)	1.85 (2.00)

significant contraction wrt DM-only case

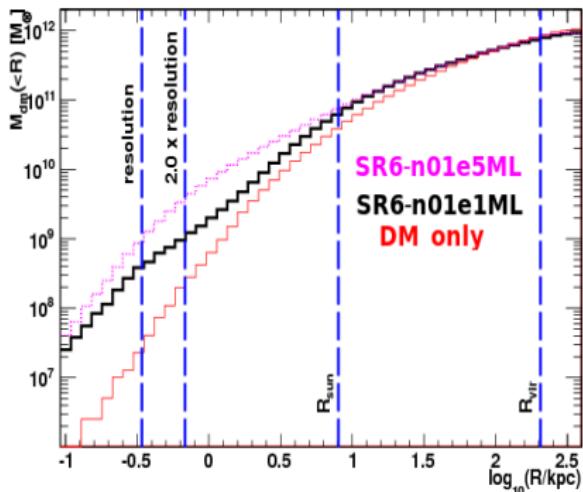

hint for an inner cusp

## [4] halo profile: mass enclosed

$M_{dm}(< 3 - 8 \text{ kpc})$ : important for dynamical constraints

insensitive to inner cusp:  $R^{-1.97}$ ,  $\tilde{R} = 3(8) \text{ kpc}$      $\Delta M_{dm}(< \tilde{R}) = 3(1)\%$

same  $M_{dm}(< 8 \text{ kpc})$  for  $\frac{\bar{\rho}_0(\text{SR6-n01e1ML})}{\bar{\rho}_0(\text{DM-only})} \simeq 0.9$

but:  $A \pm B, \Sigma_*$  constrain  $\bar{\rho}_0$  and  $M_{dm}(< R_0)$

↓  
using contracted profiles would lead to smaller  $c$ , but same  $\bar{\rho}_0$

# [+] phase space: a first look

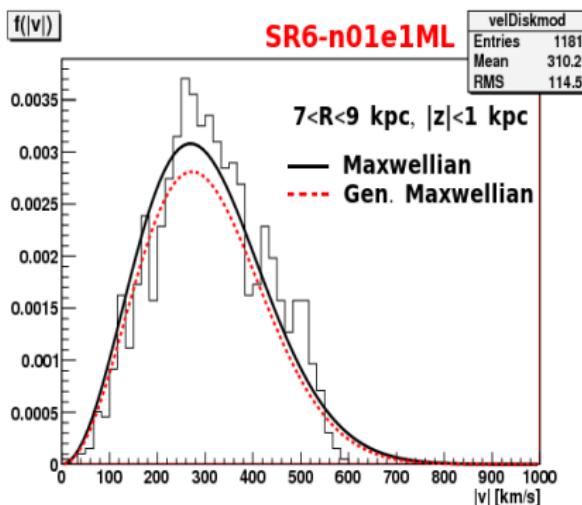

## relevance

for direct detection:  $\frac{dR}{dE} \propto \int_{v_{min}}^{\infty} dv \frac{f(v)}{v}$

for capture in astrophysical objects:  $C \propto \int_0^{v_{max}} dv \frac{f(v)}{v}$

standard approach: use Maxwellian  $f(v) = \sqrt{\frac{2}{\pi}} \frac{v^2}{\sigma^3} \exp\left(-\frac{v^2}{2\sigma^2}\right)$ ,  $\sigma = 270$  km/s

uncertainties related to mismodelling of  $f(v)$

SR6-n01e1ML

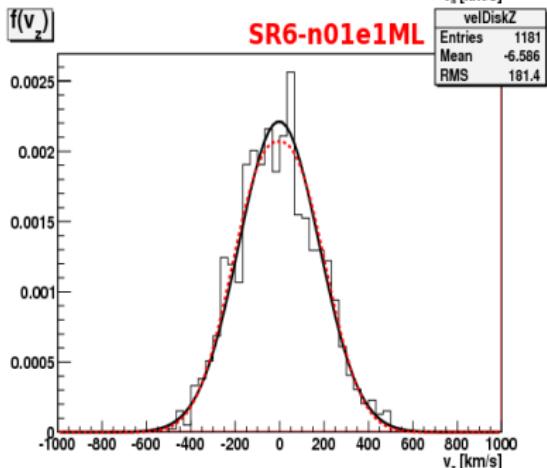

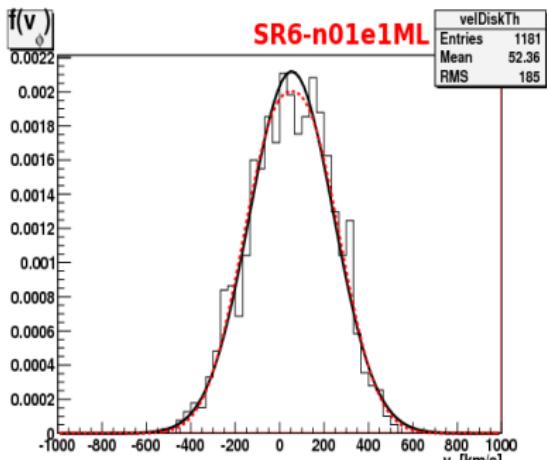

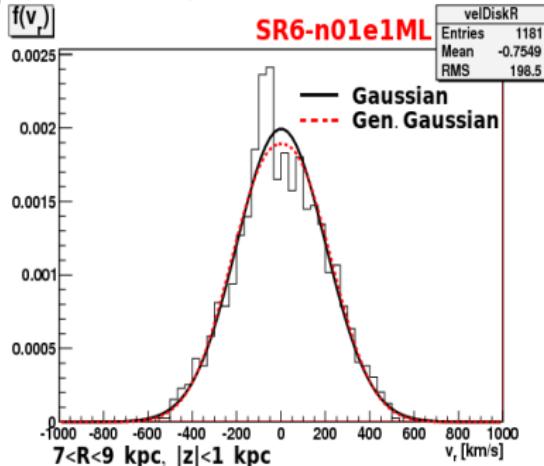

local stellar disk  $7 < R < 9$  kpc and  $|z| < 1$  kpc

$v$  wrt  $\langle v \rangle_{R < 50}$  kpc

Maxwellian and generalised Maxwellian give poor fits  $\chi^2/N_{dof} \simeq 3 - 4$

[ongoing work...]

# [+] phase space: a first look

Gaussian ok (generalised forms not needed)

$$\langle v_\phi \rangle \sim 50 \text{ km/s}$$

no dark disk apparent, but need more particles

[ongoing work...]

# [!] conclusions

$\rho_0$  in light of recent N-body+hydro simulations

halo shape:  $\lesssim 40\%$  systematics

halo profile: no shift

inner cusp? (indirect detection)

phase space: departure from Maxwellian (?)

upcoming direct detection experiments and results urge for accurate control over systematics of astrophysical parameters
