Introduction

- The interacting theory of higher spin fields was constructed by Misha Vasiliev in late 80th. [Fradkin & Vasiliev 87, Vasiliev 88-89]
- Misha's interacting massless h-spin theory is formulated with the use of noncommutative star product and has quite a complicated structure.
- Not so many exact solutions of this theory are known. The known action principle [P. Sundell, N. Boulanger, N. Colombo] is quite unusual. Some properties are to be clarified.
- This stimulates not only its extensive study, but also a search for alternative frameworks to reformulate it/to construct interacting higher spin theories.
- One of such frameworks is provided by 'tensorial superspace'.

$\Sigma(10|4)$

- Fronsdal [1985]: tensorial space

$$\Sigma^{(10|0)} = \{x^m, y^{mn}\}, \quad y^{mn} = -y^{nm} \quad m, n = 0, 1, 2, 3$$

is the natural space for the 4D massless (=)conformal higher spin theories.

- The reason is clearer if we notice that

$$\Sigma^{(10|0)} = \{X^{\alpha\beta}\}, \quad X^{\alpha\beta} = X^{\beta\alpha}, \quad \alpha, \beta = 1, \dots, 4$$

$$X^{\alpha\beta} = X^{\beta\alpha} \Rightarrow X^{\alpha\beta} = x^m \gamma_m^{\alpha\beta} + \frac{1}{2} y^{mn} \gamma_{mn}^{\alpha\beta}.$$

- The first dynamical model in the superspace generalization of $\Sigma^{(10|0)}$,

$$\Sigma^{(10|4)} = \{x^m, y^{mn}, \theta^\alpha\} = \{X^{\alpha\beta}, \theta^\alpha\}, \quad \alpha, \beta = 1, \dots, 4$$

was constructed in 1998 [I.B. + J. Lukierski MPLA 1999].

- Its quantization [I.B. + J. Lukierski + D. Sorokin 1999] gave the tower of conformal massless higher spin fields in D=4.

- Actually this 'generalized superparticle model' [I.B.+ J. Lukierski 1999] was formulated in

$$\Sigma^{(\frac{n(n+1)}{2}|n)} = \{X^{\alpha\beta}, \theta^\alpha\}, \quad \alpha, \beta = 1, \dots, n$$

where n is dim. of a min. spinor representation in D dimensions.

- It is D dimensional as far as $x^m =_{\propto} \Gamma_{\alpha\beta}^m X^{\alpha\beta}$, $m = 0, 1, \dots, (D - 1)$.
- The additional tensorial coordinates $y^{m_1 \dots m_p} =_{\propto} \Gamma_{\alpha\beta}^{m_1 \dots m_p} X^{\alpha\beta}$
- correspond to tensorial central charges of most general D-dim SUSY algebra, $\{Q_\alpha, Q_\beta\} = \mathcal{P}_{\alpha\beta} = \Gamma_{\alpha\beta}^m P_m + \Gamma_{(\alpha\beta)}^{m_1 \dots m_p} Z_{m_1 \dots m_p}$.
- Only $Z_{m_1 \dots m_p}$ with p, D obeying $\Gamma_{\alpha\beta}^{m_1 \dots m_p} = \Gamma_{(\alpha\beta)}^{m_1 \dots m_p}$ are present. Hence

D	n	$\frac{n(n+1)}{2} = \# \text{ of central charges}$	$Z_{m_1 \dots m_p}$	$y^{m_1 \dots m_p}$
4	4	$10 = 4 + 6$	Z_{mn}	y^{mn}
6	8	$36 = 6 + 30$	$Z_{mnp}^{l(=1,2,3)}$	y_l^{mnp} ,
10	16	$136 = 10 + 126$	$Z_{m_1 \dots m_5}$	$y^{m_1 \dots m_5}$
11	32	$528 = 11 + 517$	$Z_{mn}, Z_{m_1 \dots m_5}$	$y^{mn}, y^{m_1 \dots m_5}$

- The action of [I.B.+ J.L. 1999]: $S = \int d\tau \lambda_\alpha \lambda_\beta (\dot{X}^{\alpha\beta}(\tau) - i\dot{\theta}^{(\alpha}\theta^{\beta)})$
- contains a huge amount of additional coordinate functions in $X^{\alpha\beta}(\tau)$.

Preonic superparticle action

- In addition to coordinate functions $X^{\alpha\beta} = X^{\alpha\beta}(\tau)$, $\theta^\alpha = \theta^\alpha(\tau)$,

$$S = \int d\tau \mathcal{L} = \int d\tau \lambda_\alpha \lambda_\beta (\dot{X}^{\alpha\beta} - i\dot{\theta}^{(\alpha} \theta^{\beta)}) = \int \lambda_\alpha \lambda_\beta \Pi^{\alpha\beta}$$

$$\Pi^{\alpha\beta} = dX^{\alpha\beta} - id\theta^{(\alpha} \theta^{\beta)}, \quad \Pi^{\alpha\beta}(\tau) := d\tau \Pi_\tau^{\alpha\beta}$$

contains auxiliary bosonic spinor $\lambda_\alpha = \lambda_\alpha(\tau)$.

- The canonical momentum $\mathcal{P}_{\alpha\beta} := \frac{\partial \mathcal{L}}{\partial \dot{X}^{\alpha\beta}}$ is expressed through λ_α ,

$$\mathcal{P}_{\alpha\beta} = \lambda_\alpha \lambda_\beta$$

- \Leftarrow 'twistorial dimensional reduction': momentum d.o.f.s: $\frac{n(n+1)}{2} \mapsto n$.
- $4D: 10 \mapsto 4, 6D: 36 \mapsto 8, 10D: 136 \mapsto 16, 11D: 528 \mapsto 32$,
- In $D=4,6,10$ (but not in $D=11$) we have also another two effects
- $p_m \propto \mathcal{P}_{\alpha\beta} \Gamma_m^{\alpha\beta} = \lambda \Gamma_m \lambda$ is light-like, $p_m p^m = 0$. \Leftarrow famous $\Gamma_m^{(\alpha\beta} \Gamma^{\gamma\delta) a} = 0$.
- $p_m p^m = 0$ suggests that the spectrum of the quantum states of the model consists of massless particles.
- But to this end one has to prove the spectrum is discreet.

Spectrum of D=4,6,10 preonic superparticle

- In D=4,6,10, this is the case due to 'twistorial compactification':
- the spaces $\{\lambda\}/\{p^m\}_{p_n p^n=0} = \mathbb{S}^{2D-5}/\mathbb{S}^{D-2}$ is isomorphic to $\mathbb{S}^{D-3} = (\mathbb{S}^1, \mathbb{S}^3, \mathbb{S}^7)$ spheres (Hopf fibrations): $\{\lambda\}/\{p^m\}_{p_n p^n=0} = \mathbb{S}^{D-3}$
- In $D = 11$ $p_m p^m = 0$ is nonvanishing (arbitrary!) nor $\mathbb{S}^{31}/\mathbb{S}^{11}$ (nor $\mathbb{S}^{31}/\mathbb{S}^9$) is known to be a sphere (or a compact space).
- The interest to this case was due to an M-theoretical perspective ('BPS preons' [I.B., J. de Azcárraga, J. Izquierdo, J. Lukierski, 2000]).
- In $D = 4, 6, 10$ the space of additional momentum variables is compact, $\mathbb{S}^{D-3} = (\mathbb{S}^1, \mathbb{S}^3, \mathbb{S}^7)$, which implies that the spectrum of corresponding coordinate variables is discreet.
- These are helicity in $D = 4$ and its generalizations in $D = 6$ and 10.
- This implies that quantum state spectrum of the D=4,6,10 'tensorial' superparticle $S = \int d\tau \lambda_\alpha \lambda_\beta (\dot{X}^{\alpha\beta}(\tau) - i\dot{\theta}^{(\alpha}\theta^{\beta)})$ is given by the complete tower of massless higher spin fields. [I.B, J.Lukierski and D.Sorokin 99].
- Also the equations of motion for higher spin fields in $\Sigma \frac{n(n+1)}{2} |n\rangle$ can be obtained by quantizing $S = \int d\tau \lambda_\alpha \lambda_\beta (\dot{X}^{\alpha\beta} - i\dot{\theta}^{(\alpha}\theta^{\beta)})$.
- But to lighten the representation, we will go another way.

Higher spin equations in tensorial superspace

- Free equations of motion for all the field strengths of all bosonic and fermionic higher spin fields can be collected in [M. Vasiliev 2001]

$$\begin{aligned}\partial_{\alpha[\beta}\partial_{\gamma]\delta} b(X) = 0 &\Leftrightarrow (\partial_{\alpha\beta}\partial_{\gamma\delta} - \partial_{\alpha\gamma}\partial_{\beta\delta}) b(X) = 0, \\ \partial_{\alpha[\beta}f_{\gamma]}(X) = 0 &\Leftrightarrow (\partial_{\alpha\beta}f_{\gamma}(X) - \partial_{\alpha\gamma}f_{\beta}(X)) = 0.\end{aligned}$$

- where $\partial_{\alpha\beta} := \frac{1}{2} \frac{\partial}{\partial X^{\alpha\beta}}$ and $f_{\beta}(X) = f_{\beta}(X^{\alpha\beta})$ is fermionic.
- In D=4 $\{X^{\alpha\beta}\} = \{x^m, y^{mn}\}$

$$\begin{aligned}b(x, y) &= \phi(x) + y^{m_1 n_1} F_{m_1 n_1}(x) + y^{m_1 n_1} y^{m_2 n_2} \hat{R}_{m_1 n_1, m_2 n_2}(x) + \\ &\quad + \sum_{s=3}^{\infty} y^{m_1 n_1} \dots y^{m_s n_s} \hat{R}_{m_1 n_1, \dots, m_s n_s}(x), \\ f^{\alpha}(x, y) &= \psi^{\alpha}(x) + y^{m_1 n_1} \hat{\mathcal{R}}_{m_1 n_1}^{\alpha}(x) + \\ &\quad + \sum_{s=\frac{5}{2}}^{\infty} y^{m_1 n_1} \dots y^{m_{s-\frac{1}{2}} n_{s-\frac{1}{2}}} \hat{\mathcal{R}}_{m_1 n_1, \dots, m_{s-\frac{1}{2}} n_{s-\frac{1}{2}}}^{\alpha}(x).\end{aligned}$$

- $\partial_{\alpha[\beta}\partial_{\gamma]\delta} b(X) = 0 \Rightarrow \left\{ \begin{array}{l} \partial_{[m} F_{nk]} = 0, \partial_{[m_3} R_{m_1 m_2] n_1 n_2} = 0, \dots \\ \square\phi(x) = 0, \partial^m F_{mn} = 0, \partial^{m_1} R_{m_1 m_2 n_1 n_2} = 0 \dots \end{array} \right.$
- $\partial_{\alpha[\beta}f_{\gamma]}(X) = 0 \Rightarrow \{\not{\partial}\psi = 0, \dots$

Higher spin equations in 4D tensorial superspace

- In a more schematic notation $[2] := [mn] \equiv -[nm]$; $[2]_1 := [m_1 n_1]$

$$b(x, y) = \phi(x) + y^{[2]} F_{[2]}(x) + y^{[2]_1} y^{[2]_2} \hat{R}_{[2]_1 [2]_2}(x) + \sum_{s=3}^{\infty} y^{[2]_1} \dots y^{[2]_s} \hat{R}_{[2]_1 \dots [2]_s}(x),$$

$$f^\alpha(x, y) = \psi^\alpha(x) + y^{[2]} \hat{\mathcal{R}}_{[2]}^\alpha(x) + \sum_{s=\frac{5}{2}}^{\infty} y^{[2]_1} \dots y^{[2]_{s-1/2}} \hat{\mathcal{R}}_{[2]_1 \dots [2]_{s-1/2}}^\alpha(x).$$

- and eqs. for higher spin curvatures are (with $D = 4$)

$$\partial_{[m_1} R_{m_2 n_1] n_2 [2]_3 \dots [2]_s} = 0, \quad \partial^{m_1} R_{m_1 m_2, [2]_2 \dots [2]_s} = 0.$$

$$R_{[m_1 m_2 n_1] n_2 [2]_3 \dots [2]_s} = 0 \quad \Leftrightarrow \quad R = \underbrace{\begin{matrix} \square \dots \square \\ \square \dots \square \end{matrix}}_s$$

- $\Leftrightarrow R_{m_1 n_1, \dots, m_s n_s} = \sigma_{m_1}^{A_1} \sigma_{n_1}^{A_{s+1}} \dots \sigma_{m_s}^{A_s} \sigma_{n_s}^{A_{2s}} C_{A_1 \dots A_s A_{s+1} \dots A_{2s}} + c.c.$
- where symmetric spin-tensor $C_{A_1 \dots A_s A_{s+1} \dots A_{2s}}$ and its c.c. obey the Bargmann–Wigner equations

$$\partial^{BB} C_{BA_1 \dots A_{2s-1}}(x) = 0, \quad \partial^{BB} C_{\dot{B} \dot{A}_1 \dots \dot{A}_{2s-1}}(x) = 0.$$

Higher spin equations in 10D tensorial superspace

- In $D=10$ we denote $^{[5]} := [mnklp]$, $^{[5]}_1 := [m_1 n_1 k_1 l_1 p_1]$

$$b(x, y) = \phi(x) + y^{[5]} F_{[5]}(x) + y^{[5]_1} y^{[5]_2} \hat{R}_{[5]_1 [5]_2}(x) + \sum_{s=3}^{\infty} y^{[5]_1} \dots y^{[5]_s} \hat{R}_{[5]_1 \dots [5]_s}(x),$$

$$f_{\alpha}(x, y) = \psi_{\alpha}(x) + y^{[2]} \hat{\mathcal{R}}_{\alpha [5]}(x) + \sum_{s=\frac{5}{2}}^{\infty} y^{[5]_1} \dots y^{[5]_{s-1/2}} \hat{\mathcal{R}}_{\alpha [5]_1 \dots [5]_{s-1/2}}(x).$$

- and eqs. for higher spin curvatures are (with $D = 10$)

$$\partial_{[m_6} R_{m_1 \dots m_5], [\frac{D}{2}]_2 \dots [\frac{D}{2}]_s} = 0, \quad \partial^n R_{n[4]_1, [5]_2 \dots [5]_s} = 0.$$

$$R_{[6]_1 [4]_2 [5]_3 \dots [\frac{D}{2}]_s} \equiv R_{[m_1 \dots m_5 n_1] n_2 \dots n_5 [5]_3 \dots [\frac{D}{2}]_s} = 0 \Leftrightarrow R = \underbrace{\begin{matrix} \square \square \dots \square \\ \square \square \dots \square \\ \square \square \dots \square \\ \square \square \dots \square \\ \square \square \dots \square \end{matrix}}_s$$

- $\Leftrightarrow \boxed{\partial_{\alpha[\beta} \partial_{\gamma]\delta} b(X) = 0}$; fermionic counterparts $\Leftrightarrow \boxed{\partial_{\alpha[\beta} f_{\gamma]}(X) = 0}$.

On relation with preonic superparticle

- How to see the relation with preonic (tensorial superparticle)?

$$S = \int d\tau \mathcal{L} = \int d\tau \lambda_\alpha \lambda_\beta (\dot{X}^{\alpha\beta} - i\dot{\theta}^{(\alpha} \theta^{\beta)}) = \int \lambda_\alpha \lambda_\beta \Pi^{\alpha\beta}$$

- This produces the generalization of the Cartan-Penrose relation:

$$\mathcal{P}_{\alpha\beta} = \lambda_\alpha \lambda_\beta$$

- $\partial_{\alpha[\beta} \partial_{\gamma]\delta} b(X) = 0$ in the momentum representation reads

$$p_{\alpha[\beta} p_{\gamma]\delta} b(p) = 0$$

- $\Rightarrow b(p) \neq 0$ when $\text{rank}(p_{\alpha\beta}) = 1 \Leftrightarrow p_{\alpha\beta} = \lambda_\alpha \lambda_\beta$ for some λ_α .
- $\Rightarrow \partial_{\alpha[\beta} \partial_{\gamma]\delta} b(X) = 0$ is solved by $b(X) = \int d^n \lambda \Phi(X, \lambda)$, where

$$(\partial_{\alpha\beta} - i\lambda_\alpha \lambda_\beta) \Phi(X, \lambda) = 0$$

- Fermionic $\partial_{\alpha[\beta} f_{\gamma]}(X) = 0$ is solved by $f_\alpha(X) = \int d^n \lambda \lambda_\alpha \Phi(X, \lambda)$.
- "Preonic wave function" $\Phi(X, \lambda) = 0$ is not exactly wavefunction: it depends on both coordinates and momenta variables ($p_{\alpha\beta} = \lambda_\alpha \lambda_\beta$).

4D. Preonic equation and unfolding equations.

- In D=4 $\lambda_\alpha = (\lambda_A, \bar{\lambda}^{\dot{A}})$, $y^{mn} =_\alpha (\sigma^{[m}\tilde{\sigma}^{n]})_{AB} y^{AB} + c.c.$ and

$$\boxed{(\partial_{\alpha\beta} - i\lambda_\alpha\lambda_\beta)\Phi(X, \lambda) = 0} \Leftrightarrow \begin{cases} \left(\frac{\partial}{\partial x^{AB}} - i\lambda_A\bar{\lambda}_B\right)\Phi(x, y; \lambda, \bar{\lambda}) = 0, \\ \left(\frac{\partial}{\partial y^{AB}} - i\lambda_A\lambda_B\right)\Phi(x, y; \lambda, \bar{\lambda}) = 0, \\ \left(\frac{\partial}{\partial y^{A\dot{B}}} - i\bar{\lambda}_{\dot{A}}\bar{\lambda}_B\right)\Phi(x, y; \lambda, \bar{\lambda}) = 0, \end{cases}$$

- Misha Vasiliev prefers to work with a Fourier transform $C(X, y^\alpha) = \int d^n\lambda e^{i\lambda_\alpha y^\alpha} \Phi(X, \lambda)$ which obeys the unfolded eqs.

$$(\partial_{\alpha\beta} + i\frac{\partial}{\partial Y^\alpha}\frac{\partial}{\partial Y^\beta})C(X, y) = 0 \Leftrightarrow \begin{cases} \left(\frac{\partial}{\partial x^{AB}} + i\frac{\partial}{\partial Y^A}\frac{\partial}{\partial \bar{Y}^B}\right)C(x, y; Y, \bar{Y}) = 0, \\ \left(\frac{\partial}{\partial y^{AB}} + i\frac{\partial}{\partial Y^A}\frac{\partial}{\partial Y^B}\right)C(x, y; Y, \bar{Y}) = 0, \\ \left(\frac{\partial}{\partial y^{A\dot{B}}} + i\frac{\partial}{\partial \bar{Y}^A}\frac{\partial}{\partial \bar{Y}^B}\right)C(x, y; Y, \bar{Y}) = 0, \end{cases}$$

- One can show [Vasiliev 2001] that in $C(X, y) = b(X) + f_\alpha(X) y^\alpha + \sum_{n=2}^\infty C_{\alpha_1 \dots \alpha_n}(X) y^{\alpha_1} \dots y^{\alpha_n}$ the only dynamical fields are scalar $b(X)$ and spinor (or 'svector') $f_\alpha(X)$ which satisfy $\partial_{\alpha[\beta}\partial_{\gamma]\delta} b(X) = 0$ and $\partial_{\alpha[\beta} f_{\gamma]}(X) = 0$.

Superfield generalization

- Let us introduce covariant Grassmann derivative in $\Sigma^{\binom{n(n+1)}{2}|n}$

$$D_\alpha = \partial/\partial\theta^\alpha + i\theta^\beta \partial_{\beta\alpha}, \quad \{D_\alpha, D_\beta\} = 2i\partial_{\alpha\beta}.$$

- The (manifestly) $GL(n)$ covariant eq. [I.B., Pasti, Sorokin, Tonin 2004]

$$D_{[\alpha} D_{\beta]} \Phi(X, \theta) = 0$$

- \Rightarrow in $\Phi(X^{\alpha\beta}, \theta^\gamma) = b(X) + f_\alpha(X) \theta^\alpha + \sum_{i=2}^n \phi_{\alpha_1 \dots \alpha_i}(X) \theta^{\alpha_1} \dots \theta^{\alpha_i}$ the only dynamical fields are scalar $b(X)$ and spinor (or 'svector') $f_\alpha(X)$ which satisfy $\partial_{\alpha[\beta} \partial_{\gamma]\delta} b(X) = 0$ and $\partial_{\alpha[\beta} f_{\gamma]}(X) = 0$.
- Actually this equation possesses $OSp(1|2n)$ invariance ($OSp(1|8)$ for $D=4$), like $S = \int \lambda_\alpha \lambda_\beta (dX^{\alpha\beta} - id\theta^{(\alpha} \theta^{\beta)})$ does [I.B., Lukierski 98].

Superfield generalization

- The (manifestly) $GL(n)$ covariant eq. [I.B., Pasti, Sorokin, Tonin 2004]

$$D_{[\alpha} D_{\beta]} \Phi(X, \theta) = 0, \quad \{D_{\alpha}, D_{\beta}\} = 2i\partial_{\alpha\beta}$$

- \Rightarrow in $\Phi(X^{\alpha\beta}, \theta^{\gamma}) = b(X) + f_{\alpha}(X) \theta^{\alpha}$,
- $\partial_{\alpha[\beta} \partial_{\gamma]\delta} b(X) = 0$ and $\partial_{\alpha[\beta} f_{\gamma]}(X) = 0$.
- Actually this equation possesses $OSp(1|2n)$ invariance ($OSp(1|8)$ for $D=4$), like $S = \int \lambda_{\alpha} \lambda_{\beta} (dX^{\alpha\beta} - id\theta^{(\alpha} \theta^{\beta)})$ does [I.B., Lukierski 98].
- Its quantization [I.B., Lukierski, Sorokin 1999]: wave function is a **Clifford superfield** ($\chi\chi = 1, \chi\theta = -\theta\chi$)

$$\Upsilon(X, \theta, \lambda, \chi) = g_0(X, \theta, \lambda) + i\chi g_1(X, \theta, \lambda) = \Upsilon(X, \theta, -\lambda, -\chi))$$

$$\text{obeying } \boxed{(D_{\alpha} - \chi \lambda_{\alpha}) \Upsilon(X, \theta, \lambda, \chi) = 0.}$$

- $\Rightarrow (D_{\alpha} D_{\beta} + \lambda_{\alpha} \lambda_{\beta}) g_0(X, \theta, \lambda) = 0 \Rightarrow D_{[\alpha} D_{\beta]} g_0(X, \theta, \lambda) = 0$.
- $\Phi(X, \theta) = \int d^n \lambda g_0(X, \theta, \lambda) = b(X) + f_{\alpha}(X) \theta^{\alpha}$,
 $b(X) = \int d^n \lambda g_0(X, 0, \lambda)$,
 $f_{\alpha}(X) = \int d^n \lambda D_{\alpha} g_0(X, \theta, \lambda)|_{\theta=0}$,

AdS higher spin equations. Superfield form

- Thus all the free massless conformal higher spin eqs. in $D=4,6,10$ can be collected in one scalar eq. in $\Sigma^{(\frac{n(n+1)}{2}|n)}$ with $n = 4, 8, 16$:

$$\boxed{D_{[\alpha} D_{\beta]} \Phi(X, \theta) = 0} \Rightarrow \begin{cases} \Phi(X^{\alpha\beta}, \theta^\gamma) = b(X) + f_\alpha(X) \theta^\alpha, \\ \partial_{\alpha[\beta} \partial_{\gamma]\delta} b(X) = 0, \partial_{\alpha[\beta} f_{\gamma]}(X) = 0 \end{cases}$$

- Can we do this with (massless conformal) AdS higher spin equations?
- 1) What is the AdS generalization of the tensorial superspace $\Sigma^{(\frac{n(n+1)}{2}|n)}$?

- [I.B., Lukierski, Preitschopf, Sorokin 2000]: $\boxed{AdS^{(\frac{n(n+1)}{2}|n)} = OSp(1|n)}$

- In particular, $\boxed{AdS^{(10|4)} = OSp(1|4)}$

- Indeed, it is natural as far as $AdS_4 = Sp(4)/SO(1, 3)$.

- $N = 1$ AdS superspace is $AdS^{(4|4)} = OSp(4)/SO(1, 3)$.

- Abelian algebra of Z_{mn} can be considered as a contraction of $so(1, 3)$ algebra.

AdS higher spin equations. Superfield form

- Thus all the free massless conformal higher spin eqs. in $D=4,6,10$ can be collected in one scalar eq. in $\Sigma^{(\frac{n(n+1)}{2}|n)}$ with $n = 4, 8, 16$:

$$\boxed{D_{[\alpha} D_{\beta]} \Phi(X, \theta) = 0} \Rightarrow \begin{cases} \Phi(X^{\alpha\beta}, \theta^\gamma) = b(X) + f_\alpha(X) \theta^\alpha, \\ \partial_{\alpha[\beta} \partial_{\gamma]\delta} b(X) = 0, \partial_{\alpha[\beta} f_{\gamma]}(X) = 0 \end{cases}$$

- Can we do this with (massless conformal) AdS higher spin equations?

- 1) [I.B., Lukierski, Preitschopf, Sorokin 2000]: $\boxed{AdS^{(\frac{n(n+1)}{2}|n)} = OSp(1|n)}$

- 2) Free conformal AdS higher spin equations can be collected in

$$\left(\nabla_{[\alpha} \nabla_{\beta]} + i \frac{\varsigma}{4} C_{\alpha\beta} \right) \Phi(X, \theta) = 0.$$

where $\varsigma \propto \frac{1}{R_{AdS}}$, $C_{\alpha\beta} = -C_{\beta\alpha}$ is the Sp 'metric' and the $OSp(1|n)$ covariant derivatives $\nabla_\alpha, \nabla_{\alpha\beta}$ obey the $osp(1|n)$ superalgebra

$$\begin{aligned} \{\nabla_\alpha, \nabla_\beta\} &= 2i \nabla_{\alpha\beta}, & [\nabla_{\alpha\alpha'}, \nabla_\beta] &= \varsigma C_{\beta(\alpha} \nabla_{\alpha')}, \\ [\nabla_{\alpha\beta}, \nabla_{\gamma\delta}] &= \varsigma C_{\alpha(\gamma} \nabla_{\delta)\beta} + \varsigma C_{\beta(\gamma} \nabla_{\delta)\alpha}. \end{aligned}$$

AdS higher spin equations. Component form on $Sp(n)$ space

- $$\boxed{(\nabla_{[\alpha} \nabla_{\beta]} + i \frac{\zeta}{4} C_{\alpha\beta}) \Phi(X, \theta) = 0} \Rightarrow \text{'component equations on } Sp(n)$$

[Sorokin, Plyushchay, Tsulaia 2003]

$$\begin{aligned} \nabla_{\alpha[\beta} \nabla_{\gamma]\delta} b(X) &= \frac{\zeta}{4} (C_{\alpha[\beta} \nabla_{\gamma]\delta} + C_{\delta[\beta} \nabla_{\gamma]\alpha} - C_{\beta\gamma} \nabla_{\alpha\delta}) b(X) + \\ &\quad + \frac{\zeta^2}{16} (C_{\alpha\delta} C_{\beta\gamma} - C_{\alpha[\beta} C_{\gamma]\delta}) b(X), \\ \nabla_{\alpha[\beta} f_{\gamma]}(X) &= -\frac{\zeta}{4} (C_{\alpha[\gamma} f_{\beta]}(X) + C_{\beta\gamma} f_{\alpha}(X)). \end{aligned}$$

where $[\nabla_{\alpha\beta}, \nabla_{\gamma\delta}] = \zeta C_{\alpha(\gamma} \nabla_{\delta)\beta} + \zeta C_{\beta(\gamma} \nabla_{\delta)\alpha}$.

- The counterpart of the Clifford superfield eq. $(D_{\alpha} - \chi \lambda_{\alpha}) \Upsilon = 0$,

$$(\nabla_{\alpha} - \chi Y_{\alpha}) \Upsilon(X, \theta, \lambda, \chi) = 0, \quad Y_{\alpha} = \lambda_{\alpha} - \frac{i\zeta}{4} C_{\alpha\beta} \frac{\partial}{\partial \lambda_{\beta}}.$$

was studied in [Didenko, Vasiliev 2003].

- To be more precise, they studied its Fourier transform

$$(\nabla_{\alpha} - \chi Y_{\alpha}) \Upsilon(X, \theta, y^{\beta}, \chi) = 0, \quad Y_{\alpha} \equiv i \frac{\partial}{\partial y^{\alpha}} + C_{\alpha\beta} \frac{\zeta}{4} y^{\beta}.$$

AdS higher spin equations. Component form on $Sp(n)$ space

$$(\nabla_\alpha - \chi Y_\alpha) \Upsilon(X, \theta, \lambda, \chi) = 0, \quad Y_\alpha = \lambda_\alpha - \frac{i\zeta}{4} C_{\alpha\beta} \frac{\partial}{\partial \lambda_\beta}.$$

- It results in an 'AdS preonic' equation ($Y = g_0 + \chi g_1$)

$$[\nabla_{\alpha\beta} - iY_{(\alpha} Y_{\beta)}] g_0(X, \theta, \lambda) = 0, \quad Y_\alpha \equiv \lambda_\alpha - \frac{i\zeta}{4} \frac{\partial}{\partial \lambda_\alpha},$$

- and in a more general

$$(\nabla_\alpha \nabla_\beta + Y_\beta Y_\alpha) g_0(X, \theta, \lambda) = 0, \quad Y_\alpha = \lambda_\alpha - \frac{i\zeta}{4} C_{\alpha\beta} \frac{\partial}{\partial \lambda_\beta}.$$

which also includes $(\nabla_{[\alpha} \nabla_{\beta]} + i\frac{\zeta}{4} C_{\alpha\beta}) g_0(X, \theta, \lambda) = 0$

- Then, $\Phi(X, \theta) = \int d^n \lambda g_0(X, \theta, \lambda)$ obeys the superfield version of the AdS higher spin equation

$$\boxed{(\nabla_{[\alpha} \nabla_{\beta]} + i\frac{\zeta}{4} C_{\alpha\beta}) \Phi(X, \theta) = 0}.$$

Preonic superparticle on $OSp(1|n)$

- $(\nabla_\alpha - \chi Y_\alpha)\Upsilon(X, \theta, \lambda, \chi) = 0$ with $Y_\alpha = \lambda_\alpha - \frac{i\zeta}{4} C_{\alpha\beta} \frac{\partial}{\partial \lambda_\beta}$ ($= \lambda_\alpha * \dots$) can be obtained by quantization of $OSp(1|n)$ superparticle

$$S = \int_{W^1} \lambda_\alpha \lambda_\beta \hat{\mathcal{E}}^{\alpha\beta} = \int d\tau \lambda_\alpha \lambda_\beta \partial_\tau \hat{Z}^M \mathcal{E}_M^{\alpha\beta}(\hat{Z}(\tau)),$$

- where $\mathcal{E}^{\alpha\beta} = dZ^M \mathcal{E}_M^{\alpha\beta}(Z)$ and $\mathcal{E}^\alpha = dZ^M \mathcal{E}_M^\alpha(Z)$ obey

$$\begin{aligned} d\mathcal{E}^{\alpha\beta} &= -i\mathcal{E}^\alpha \wedge \mathcal{E}^\beta - \zeta \mathcal{E}^{\alpha\gamma} \wedge \mathcal{E}^{\delta\beta} C_{\gamma\delta}, \\ d\mathcal{E}^\alpha &= -\zeta \mathcal{E}^{\alpha\gamma} \wedge \mathcal{E}^\delta C_{\gamma\delta}, \end{aligned}$$

- $Z^M = (X^{\check{\alpha}\check{\beta}}, \theta^{\check{\alpha}})$ are local coordinates of $OSp(1|n)$ supergroup manifold
- and $Z^M = \hat{Z}^M(\tau)$ defines the embedding of W^1 in $OSp(1|n)$.
- This action possesses rigid $OSp(1|2n)$ symmetry (generalized conformal symm.) and also $(n-1)$ local fermionic κ -symmetries (3 in D=4):

$$\delta_\kappa \hat{Z}^M \mathcal{E}_M^{\alpha\beta}(\hat{Z}) = 0, \quad \delta_\kappa \hat{Z}^M \mathcal{E}_M^\alpha(\hat{Z}) \lambda_\alpha = 0.$$

Preonic superparticle on $OSp(1|n)$ and on $\Sigma^{(n(n+1)/2|n)}$

- These symmetries survive - and become simpler- in flat SSP limit

$$OSp(1|n) \xrightarrow{\zeta \rightarrow 0} \Sigma^{(\frac{n(n+1)}{2}|n)}, \quad \mathcal{E}^{\alpha\beta} \xrightarrow{\zeta \rightarrow 0} \Pi^{\alpha\beta} = dX^{\alpha\beta} - id\theta^{(\alpha} \theta^{\beta)}, \quad \mathcal{E}^\alpha \xrightarrow{\zeta \rightarrow 0} d\theta^{(\alpha},$$

$$\left. \begin{aligned} d\mathcal{E}^{\alpha\beta} &= -i\mathcal{E}^\alpha \wedge \mathcal{E}^\beta - \zeta \mathcal{E}^{\alpha\gamma} \wedge \mathcal{E}^{\delta\beta} \mathbf{C}_{\gamma\delta}, \\ d\mathcal{E}^\alpha &= -\zeta \mathcal{E}^{\alpha\gamma} \wedge \mathcal{E}^\delta \mathbf{C}_{\gamma\delta}, \end{aligned} \right\} \xrightarrow{\zeta \rightarrow 0} \left\{ \begin{aligned} d\Pi^{\alpha\beta} &= -id\theta^\alpha \wedge d\theta^\beta, \\ dd\theta^\alpha &\equiv 0, \end{aligned} \right.$$

- The κ -symmetry of the $\Sigma^{(n(n+1)/2|n)}$ superparticle action

$$S = \int_{W^1} \lambda_\alpha \lambda_\beta \hat{\Pi}^{\alpha\beta} = \int d\tau \lambda_\alpha \lambda_\beta (\partial_\tau X^{\alpha\beta} - i\partial_\tau \theta^{(\alpha} \theta^{\beta)}) \quad \text{reads}$$

$$\delta_\kappa X^{\alpha\beta} = i\delta_\kappa \theta^{(\alpha} \theta^{\beta)}, \quad \delta_\kappa \theta^\alpha \lambda_\alpha = 0.$$

- $\delta_\kappa \theta^\alpha \lambda_\alpha = 0$ can be solved in terms of $(n - 1)$ bosonic spinors 'orthogonal' to λ_α : $\delta_\kappa \theta^\alpha = \kappa^l u_l^\alpha$, $u_l^\alpha \lambda_\alpha = 0$, $l = 1, \dots, 15$.
- This makes clear that we can gauge away all but one component of $\theta^\alpha(\tau)$: $\boxed{\eta = \theta^\alpha(\tau) \lambda_\alpha}$ which is κ -invariant.
- This is related to global $OSp(1|2n)$ symmetry of the system
- but also shows that its ground state preserves all but one SUSY
- \equiv is a BPS preon [I.B., de Azcárraga, Izquierdo, Lukierski, 2001].

κ symmetry and preserved SUSY, or Why tensorial superparticle is preonic?

- $S = \int_W \lambda_\alpha \lambda_\beta \hat{\Pi}^{\alpha\beta} = \int d\tau \lambda_\alpha \lambda_\beta (\partial_\tau X^{\alpha\beta} - i\partial_\tau \theta^{(\alpha} \theta^{\beta)})$ is invariant
- under κ -symmetry $\delta_\kappa X^{\alpha\beta} = i\delta_\kappa \theta^{(\alpha} \theta^{\beta)}$, $\delta_\kappa \theta^\alpha = \kappa^\alpha$, $\kappa^\alpha \lambda_\alpha = 0$
- and under rigid SUSY $\delta_\epsilon X^{\alpha\beta} = -i\delta_\epsilon \theta^{(\alpha} \theta^{\beta)}$, $\delta_\epsilon \theta^\alpha = \epsilon^\alpha$
- Thus $\delta\theta^\alpha = \delta_\kappa \theta^\alpha + \delta_\epsilon \theta^\alpha = \kappa^\alpha + \epsilon^\alpha$, $\kappa^\alpha \lambda_\alpha = 0$
- In the ground state of the system fermions are equal to zero: $\theta^\alpha = 0$
- so that it can be preserved by symmetries which preserve $\theta^\alpha = 0$, i.e.
- which obey $0 = \delta\theta^\alpha = \kappa^\alpha + \epsilon^\alpha$, $\kappa^\alpha \lambda_\alpha = 0$.
- This identifies all but one SUSY parameters with nontrivial parameters of κ -symmetry, $\epsilon^\alpha = -\kappa^\alpha$ and set to zero only one linear combination of the components of ϵ^α : $\epsilon^\alpha \lambda_\alpha = 0$.
- Thus all but one target space supersymmetry are preserved by the ground state of the tensorial superparticle.
- This ground state is $\frac{n-1}{n}$ BPS, i.e. $\frac{3}{4}$ BPS in D=4, $\frac{15}{16}$ BPS in D=10 and $\frac{31}{32}$ BPS in D=11;
- this is to say it is a BPS preon [I.B., de Azcárraga, Izquierdo, Lukierski, 2001].

OSp(1|2n) symmetry of $\Sigma^{(\frac{n(n+1)}{2}|n)}$ superparticle

- $S = \int_{W^1} \lambda_\alpha \lambda_\beta \hat{\Pi}^{\alpha\beta} = \int \lambda_\alpha \lambda_\beta (d\hat{X}^{\alpha\beta} - id\hat{\theta}^{(\alpha} \hat{\theta}^{\beta)})$ can be rewritten as

$$S = \int_{W^1} (\lambda_\alpha d\mu^\alpha - \mu^\alpha d\lambda_\alpha - id\chi\chi), \quad \begin{cases} \mu^\alpha = \hat{X}^{\alpha\beta} \lambda_\beta - \frac{i}{2} \hat{\theta}^\alpha \chi, \\ \chi = \hat{\theta}^\alpha \lambda_\alpha \end{cases},$$

[I.B.+Lukierski 98] or equivalently as

$$S = \int_{W^1} d\Upsilon^\Sigma \Xi_{\Sigma\Omega} \Upsilon^\Omega, \quad \Upsilon^\Sigma = \begin{pmatrix} \mu^\alpha \\ \lambda_\alpha \\ \chi \end{pmatrix}, \quad \Xi_{\Sigma\Omega} = \begin{pmatrix} 0 & \delta_\alpha^\beta & 0 \\ -\delta_\alpha^\beta & 0 & 0 \\ 0 & 0 & -i \end{pmatrix},$$

[I.B.+Lukierski 98]. Here $\Xi_{\Sigma\Omega}$ is the OSp(1|2n) 'metric' Υ^Σ is orthosymplectic supertwistor

- carrying the index of the fundamental representation of OSp(1|2n).
- Thus $S = \int_{W^1} \lambda_\alpha \lambda_\beta \hat{\Pi}^{\alpha\beta} = \int_{W^1} d\Upsilon^\Sigma \Xi_{\Sigma\Omega} \Upsilon^\Omega$ is manifestly OSp(1|2n) invariant.

$OSp(1|2n)$ symmetry of $OSp(1|n)$ superparticle from GL flatness of $OSp(1|n)$ supergroup manifold

- The simplest way to show the $OSp(1|2n)$ symmetry of $OSp(1|n)$ superparticle $S = \int_{W^1} \lambda_\alpha \lambda_\beta \hat{\mathcal{E}}^{\alpha\beta}$ is to use the GL(n) flatness of $OSp(1|n)$
- [Plyushchay, Sorokin, Tsulaia 2003]:

$$\boxed{\mathcal{E}^{\alpha\beta} = \Pi^{\alpha\beta} \mathcal{G}_\gamma^\alpha(X, \theta) \mathcal{G}_\delta^\beta(X, \theta)}, \quad \mathcal{E}^\alpha = e^{\rho(x, \theta)} (\mathcal{D}\theta^\alpha - \theta^\alpha \mathcal{D}\rho)$$

$$\mathcal{G}_\beta^\alpha(x, \theta) = G_\beta^\alpha(x) - \frac{i\zeta}{4} (\Theta_\beta - 2G_\beta^\gamma(x)\Theta_\gamma) \Theta^\alpha,$$

$$G_\beta^{-1\alpha}(x) = \delta_\beta^\alpha + \frac{\zeta}{2} x_\beta^\alpha,$$

$$\theta^\alpha = \Theta^\beta G_\beta^{-1\alpha}(x) e^{-\rho(\Theta)}, \quad e^{\rho(\Theta)} = \sqrt{1 + \frac{i\zeta}{4} \Theta^\beta \Theta_\beta},$$

$$\mathcal{D}\theta^\alpha = d\theta^\alpha - \zeta \theta^\gamma C_{\gamma\beta} \mathcal{E}^{\beta\alpha}(X, 0) = d\theta^\alpha - \zeta \theta^\gamma C_{\gamma\beta} (G^T X G)^{\beta\alpha}.$$

- Hence $S = \int_{W^1} \lambda_\alpha \lambda_\beta \hat{\mathcal{E}}^{\alpha\beta} = \int_{W^1} \tilde{\lambda}_\alpha \tilde{\lambda}_\beta \hat{\Pi}^{\alpha\beta}$ with $\tilde{\lambda}_\alpha = \mathcal{G}_\alpha^\beta(X, \theta) \lambda_\beta$
- and $OSp(1|2n)$ superconformal invariance of the $OSp(1|n)$ superparticle follows from the $OSp(1|2n)$ superconformal invariance of the $\Sigma^{\binom{n(n+1)}{2}|n}$ superparticle.

Geometry of curved tensorial superspace

- Tensorial supergravity, a theory dynamical curved tensorial superspace $\mathcal{M}^{(\frac{n(n+1)}{2}|n)}$ is a natural candidate for interacting higher spin theory.
- $Z^M = (X^{\check{\alpha}\check{\beta}}, \theta^{\check{\gamma}})$ are local coordinates of $\mathcal{M}^{(\frac{n(n+1)}{2}|n)}$. We construct the theory from the objects which are invariant under superdiffeomorphisms, $Z'^M = f^M(Z^N)$: ($\text{sdet}(\partial f^M / \partial Z^N) \neq 0$):
- Supervielbein one forms $E^{\mathcal{A}} = (E^{\alpha\beta}, E^\alpha) = dZ^M E_M^{\mathcal{A}}(Z)$

$$E^{\alpha\beta}(Z) = E^{\beta\alpha}(Z) = dZ^M E_M^{\alpha\beta}(Z), \quad E^\alpha(Z) = dZ^M E_M^\alpha(Z)$$

- And $GL(n)$ connection $\Omega_\beta^\alpha := dZ^M \Omega_{M\beta}^\alpha \equiv E^{\mathcal{A}} \Omega_{\mathcal{A}\beta}^\alpha$,
- The torsion and $GL(n)$ curvature 2-forms

$$T^{\alpha\beta} := \mathcal{D}E^{\alpha\beta} \equiv dE^{\alpha\beta} - 2E^{(\alpha|\gamma} \wedge \Omega_\gamma^{|\beta)} =: \frac{1}{2} E^\beta \wedge E^\alpha T_{AB}^{\alpha\beta},$$

$$T^\alpha := \mathcal{D}E^\alpha \equiv dE^\alpha - E^\beta \wedge \Omega_\beta^\alpha =: \frac{1}{2} E^\beta \wedge E^\alpha T_{AB}^\alpha,$$

$$\mathcal{R}_\beta^\alpha := d\Omega_\beta^\alpha - \Omega_\beta^\gamma \wedge \Omega_\gamma^\alpha =: \frac{1}{2} E^\beta \wedge E^\alpha \mathcal{R}_{AB\beta}^\alpha.$$

Superparticle in curved tensorial superspace

- As in the case of SUGRA in usual SSP we need to restrict the supervielbein and connection by superspace constraints.
- Their essential part can be obtained by the condition of preservation of the κ -symmetry of the preonic superparticle in curved tensorial SSP [I.B., Pasti, Sorokin, Tonin JHEP 2004]
- Its action $S = \int_{W^1} \lambda_\alpha \lambda_\beta \hat{E}^{\alpha\beta}$ possesses the κ -symmetry

$$\delta_\kappa \hat{Z}^M E_M^{\alpha\alpha'}(\hat{Z}) = 0, \quad \delta_\kappa \lambda_\alpha = 0, \quad \delta_\kappa Z^M E_M^\alpha(\hat{Z}) \lambda_\alpha = 0, \quad \Leftrightarrow$$

$$\Leftrightarrow \delta_\kappa \hat{Z}^M E_M^\alpha(\hat{Z}) = \mu^{\alpha I} \kappa_I(\tau), \quad I = 1, \dots, 15, \quad \mu^{\alpha I} \lambda_\alpha = 0$$

provided supervielbein is restricted by torsion constraints

$$T^{\alpha\beta} = -iE^\alpha \wedge E^\beta - 2E^{(\alpha} \wedge E^{\beta)\gamma} t_\gamma(Z) + 2E^{\gamma(\alpha} \wedge E^{\beta)\delta} R_{\gamma\delta}(Z),$$

with some fermionic $t_\gamma(Z)$ and bosonic $R_{\gamma\delta}(Z) = -R_{\delta\gamma}(Z)$.

- As usually, the theory is still reducible and we need to impose also a number of conventional constraints, counterparts of $T_{cb}{}^a = 0$ in General Relativity. One of this can be $t_\gamma(Z) = 0$, but there are a number of others.

SUGRA constraints and their consequences

- After imposing the essential and conventional constraints and studying their consistency conditions given by Bianchi identities

$$\begin{aligned} \mathcal{D}T^{\alpha\beta} + E^{\alpha\gamma} \wedge \mathcal{R}_{\gamma}{}^{\beta} + E^{\beta\gamma} \wedge \mathcal{R}_{\gamma}{}^{\alpha} &\equiv 0, \\ \mathcal{D}T^{\alpha} + E^{\beta} \wedge R_{\beta}{}^{\alpha} &\equiv 0, \\ \mathcal{D}R_{\beta}{}^{\alpha} &\equiv 0 \end{aligned}$$

- the torsion and curvature 2-forms are expressed by

$$\begin{aligned} T^{\alpha\beta} &= -iE^{\alpha} \wedge E^{\beta} + 2E^{\gamma(\alpha} \wedge E^{\beta)\delta} R_{\gamma\delta}(Z), \\ T^{\alpha} &= 2E^{\alpha\beta} \wedge E^{\gamma} R_{\beta\gamma} + E^{\alpha\beta} \wedge E^{\gamma\delta} U_{\beta\gamma\delta}, \\ R_{\beta}{}^{\alpha} &= iE^{\gamma\delta} \wedge E^{\alpha} U_{\beta\gamma\delta} - E^{\alpha\gamma} \wedge E^{\delta} (F_{\delta\beta\gamma} + \mathcal{D}_{\delta} R_{\beta\gamma}) - \\ &\quad - E^{\alpha\gamma} \wedge E^{\delta\epsilon} (\mathcal{D}_{(\beta} U_{\gamma)\delta\epsilon} + \mathcal{D}_{\delta\epsilon} R_{\beta\gamma}). \end{aligned}$$

- in terms of 'main superfields' $R_{\beta\alpha} = -R_{\alpha\beta}$, $U_{\beta\gamma\delta} = U_{\beta(\gamma\delta)}$ and $F_{\alpha\beta\gamma} = 2iU_{(\beta\gamma)\alpha} - iU_{\alpha\beta\gamma} - 2\mathcal{D}_{(\beta} R_{\gamma)\alpha}$ which obey a number of relations

$$\begin{aligned} \mathcal{D}_{[\alpha} U_{\beta]\gamma\delta} &= -\mathcal{D}_{\gamma\delta} R_{\alpha\beta}, \quad \mathcal{D}_{(\alpha} U_{\beta)\gamma\delta} = -i\mathcal{D}_{(\gamma} F_{\delta)\alpha\beta} \\ \mathcal{D}_{\alpha\beta} U_{\gamma\delta\sigma} - \mathcal{D}_{\delta\sigma} U_{\gamma\alpha\beta} + 2U_{\gamma\alpha(\sigma} R_{\delta)\beta} + 2U_{\gamma\beta(\sigma} R_{\delta)\alpha} &= 0, \end{aligned}$$

SUGRA constraints and their solutions

- The constraints $T^{\alpha\beta} = -iE^\alpha \wedge E^\beta + 2E^{\gamma(\alpha} \wedge E^{\beta)\delta} R_{\gamma\delta}(Z)$,

$$\begin{aligned} T^\alpha &= 2E^{\alpha\beta} \wedge E^\gamma R_{\beta\gamma} + E^{\alpha\beta} \wedge E^{\gamma\delta} U_{\beta\gamma\delta} , \\ \mathcal{R}_{\beta}{}^\alpha &= iE^{\gamma\delta} \wedge E^\alpha U_{\beta\gamma\delta} - E^{\alpha\gamma} \wedge E^\delta (F_{\delta\beta\gamma} + \mathcal{D}_\delta R_{\beta\gamma}) - \\ &\quad - E^{\alpha\gamma} \wedge E^{\delta\epsilon} (\mathcal{D}_{(\beta} U_{\gamma)\delta\epsilon} + \mathcal{D}_{\delta\epsilon} R_{\beta\gamma}) . \end{aligned}$$

- have $\Sigma^{\binom{n(n+1)}{2}|n}$ solution: $R_{\gamma\delta} = 0$ and $U_{\gamma\delta\epsilon} = 0$ ($\} \Rightarrow F_{\gamma\delta\epsilon} = 0$).
- Setting $R_{\alpha\beta} = -\frac{\zeta}{2} C_{\alpha\beta}$ and $U_{\alpha\beta\gamma}(Z) = 0$ we find $\mathcal{R}_\alpha{}^\beta = 0 \Rightarrow$ we can gauge away $GL(n)$ connection ($\Omega_\alpha{}^\beta = 0$) and arrive at

$$\begin{aligned} d\mathcal{E}^{\alpha\beta} &= -i\mathcal{E}^\alpha \wedge \mathcal{E}^\beta - \zeta \mathcal{E}^{\alpha\gamma} \wedge \mathcal{E}^{\delta\beta} C_{\gamma\delta} , \\ d\mathcal{E}^\alpha &= -\zeta \mathcal{E}^{\alpha\gamma} \wedge \mathcal{E}^\delta C_{\gamma\delta} . \end{aligned}$$

which are the Maurer–Cartan eqs. for $OSp(1|n)$.

- Thus $OSp(1|n)$ supergroup manifold is also a solution of the TSSP SUGRA constraints.

Scalar superfield eq. in SUGRA background and reduction of the holonomy group to $SL(n)$

- A natural generalization of the free superfield equations for higher spin fields to curved TSSP is $\mathcal{D}_{[\alpha} \mathcal{D}_{\beta]} \Phi = \frac{i}{2} R_{\alpha\beta} \Phi$.
- Its integrability condition results in a quite complicated equation
- the known solution of which reduces the holonomy group from $GL(n, \mathbb{R})$ to $SL(n, \mathbb{R})$ i.e. implies $\mathcal{R}_\alpha^\alpha = 0$.
- Such a reduction simplifies a bit equations for main superfields,
- but also makes possible to prove [I.B., Pasti, Sorokin, Tonin 2004]:
- the general solution of supergravity constraints is superconformally equivalent either to $OSp(1|n)$ or to the flat $\Sigma^{(\frac{n(n+1)}{2}|n)}$.
- Namely, they can be obtained by

$$\begin{aligned}
 E'^{\alpha\beta} &= E^{\alpha\beta}, & E'^\alpha &= E^\alpha + E^{\alpha\beta} W_\beta \\
 \Omega'_\beta{}^\alpha &= \Omega_\beta{}^\alpha - iE^\alpha W_\beta - E^{\alpha\gamma} (\mathcal{D}_\gamma W_\beta + iW_\gamma W_\beta),
 \end{aligned}$$

with $W_\beta = -i\mathcal{D}_\beta W$ (and $GL(n)$ gauge transformations, $e^{kW} \delta_\alpha^\beta$, if convenient) from flat or OSp supervielbein and (trivial) $GL(n)$ connection.

Solution of SL(n) SUGRA in TSSP are superconformally OSp or superconformally flat

- The general solution for the main superfields

$$R_{\alpha\beta} = i e^{-\frac{2W}{n}} \left[i \frac{\zeta}{2} C_{\alpha\beta} + \nabla_{[\alpha} \nabla_{\beta]} W + \frac{1}{2} \nabla_{\alpha} W \nabla_{\beta} W \right],$$

$$U_{\beta\gamma\delta} = e^{-\frac{3W}{n}} \left[-i \nabla_{\gamma\delta} \nabla_{\beta} W + \nabla_{(\gamma} W \nabla_{\delta)} \nabla_{\beta} W \right].$$

- Note: the original OSp solution, $R_{\alpha\beta} = -\frac{\zeta}{2} C_{\alpha\beta}$ and $U_{\alpha\beta\gamma}(Z) = 0$ is preserved by superWeyl (supplemented by certain $GL(n)$ gauge) transformations if the superfield parameter W obeys

$$\nabla_{[\alpha} \nabla_{\beta]} W + \frac{1}{2} \nabla_{\alpha} W \nabla_{\beta} W = -\frac{i\zeta}{2} C_{\alpha\beta} \left(1 - e^{-\frac{W}{2}} \right)$$

- which is an equivalent form of the free eqs, for the free higher spin fields in AdS: $W = 2 \ln \left(\frac{\Phi+a}{a} \right)$ where $a = \text{const} > 0$ and $\Phi(X, \theta)$ obeys

$$\left(\nabla_{[\alpha} \nabla_{\beta]} + i \frac{\zeta}{4} C_{\alpha\beta} \right) \Phi(X, \theta) = 0.$$

- However, the conclusion is that **supergravity in tensorial superspace is super-Weyl trivial**: It does not describe dynamical potentials of higher spin supergravity and describes, at most, the free higher spin eqs.

super-Weyl triviality of SUGRA in TSSP and possible ways out

- **Supergravity in tensorial superspace, as it has been formulated, is super-Weyl trivial** \Rightarrow It does not describe dynamical potentials of higher spin SUGRA and describes, at most, the free higher spin eqs.
- Some deformation of the theory or introduction of new elements are needed to continue the search for interacting HSpin theory on this basis.
- Ex.: current project with Dima Sorokin and Per Sundel. To start form an a-deformed 4D tensorial superparticle [I.B., J. Lukierski and D. Sorokin 1999]. SUGRA constraints from preservation of its 2 (not 3) κ -symmetries.
- Other basis to construct interacting higher spin theories in tensorial SSP. Tensorial SYM?
- YM field appears in the multiplets of extended SUSY. \Rightarrow some interest superfield theories in extended TSSP. These were studied in [I.B., J. de Azcárraga, C. Meliveo, 2011].

HSpin equations in \mathcal{N} -extended tensorial superspaces

- Higher spin equations in extended tensorial superspaces

$$\Sigma^{\binom{n(n+1)}{2}|\mathcal{N}n} = \{Z^M\} = \{(X^{\alpha\beta}, \theta^{\alpha l})\}, \quad \begin{cases} \alpha, \beta = 1, \dots, n, \\ l = 1, \dots, \mathcal{N} \end{cases}$$

for even \mathcal{N} : [I.B., J. de Azcárraga, C. Meliveo, 2011]

- is convenient to write in terms of complex fermionic coordinates

$$\Theta^{\alpha q} = \frac{1}{2}(\theta^{\alpha q} - i\theta^{\alpha(q+\mathcal{N}/2)}) = (\bar{\Theta}_q^\alpha)^*, \quad q = 1, \dots, \mathcal{N}/2,$$

$$\partial_{\alpha q} := \frac{\partial}{\partial \Theta^{\alpha q}} = \frac{\partial}{\partial \theta^{\alpha q}} + i \frac{\partial}{\partial \theta^{\alpha(q+\mathcal{N}/2)}},$$

and complex fermionic covariant derivatives,

$$\mathcal{D}_{\alpha q} = \partial_{\alpha q} + 2i\partial_{\alpha\beta}\bar{\Theta}_q^\beta, \quad \bar{\mathcal{D}}_\alpha{}^q = \bar{\partial}_\alpha{}^q + 2i\partial_{\alpha\beta}\Theta^{\beta q}, \quad \partial_{\alpha q} := \frac{\partial}{\partial \Theta^{\alpha q}},$$

$$\boxed{\{\mathcal{D}_{\alpha q}, \bar{\mathcal{D}}_\beta{}^p\} = 4i\partial_{\alpha\beta}\delta_q^p}, \quad \{\mathcal{D}_{\alpha q}, \mathcal{D}_\beta{}^p\} = 0 = \{\bar{\mathcal{D}}_\alpha{}^q, \bar{\mathcal{D}}_\beta{}^p\}.$$

- The free higher spin equations with extended SUSY read

$$\bar{\mathcal{D}}_\alpha{}^q \Phi(X, \Theta^{q'}, \bar{\Theta}_{p'}) = 0, \quad \mathcal{D}_{q[\beta} \mathcal{D}_{\gamma]p} \Phi(X, \Theta^{q'}, \bar{\Theta}_{p'}) = 0.$$

HSpin equations with $\mathcal{N} = 2$ -extended supersymmetry

- The superfield equations

$$\bar{D}_\alpha^q \Phi(X, \Theta, \bar{\Theta}) = 0, \quad \mathcal{D}_{q[\beta} \mathcal{D}_{\gamma]p} \Phi(X, \Theta, \bar{\Theta}) = 0.$$

- For $\mathcal{N} = 2$: \Rightarrow

$$\Phi(X, \Theta, \bar{\Theta}) = \phi(X_L) + i\Theta^\alpha \psi_\alpha(X_L)$$

with $X_L^{\alpha\beta} = X^{\alpha\beta} + 2i\Theta^{(\alpha} \bar{\Theta}^{\beta)}$ (notice that $n=4$ for $D=4$) and

$$\partial_{\alpha[\gamma} \partial_{\delta]\beta} \phi(X) = 0, \quad \partial_{\alpha[\beta} \psi_{\gamma]}(X) = 0.$$

HSpin equations with $\mathcal{N} = 4$ -extended supersymmetry

- The superfield equations

$$\bar{D}_\alpha^q \Phi(X, \Theta, \bar{\Theta}) = 0, \quad \mathcal{D}_{q[\beta} \mathcal{D}_{\gamma]p} \Phi(X, \Theta, \bar{\Theta}) = 0.$$

- For $\mathcal{N} = 4$: \Rightarrow

$$\Phi(X, \Theta^q, \bar{\Theta}_q) = \phi(X_L) + i\Theta^{\alpha q} \psi_{\alpha q}(X_L) + \epsilon_{pq} \Theta^{\alpha q} \Theta^{\beta p} \mathcal{F}_{\alpha\beta}(X_L)$$

$$\partial_{\alpha[\gamma} \partial_{\delta]\beta} \phi(X) = 0, \quad \partial_{\alpha[\beta} \psi_{\gamma]q}(X) = 0,$$

and $\mathcal{F}_{\alpha\beta} = \mathcal{F}_{\beta\alpha}$ obeying $\partial_{\alpha[\gamma} \mathcal{F}_{\delta]\beta}(X) = 0$

- It might seem that we have found a tensorial superspace counterparts of the usual Maxwell equations and Bianchi identities

$$\partial_{A[\dot{B}} F_{C]D} = 0, \quad \partial_{A[\dot{B}} \dot{F}_{\dot{C}]D} = 0. \quad (1)$$

- However, the general solution of this tensorial space equation is

$$\mathcal{F}_{\alpha\beta} = \partial_{\alpha\beta} \tilde{\phi}(X), \quad \partial_{\alpha[\gamma} \partial_{\delta]\beta} \tilde{\phi}(X) = 0.$$

- Peccei-Quinn-like symmetry acting on the second scalar field $\tilde{\phi}(X)$:
 $\tilde{\phi}(X) \mapsto \tilde{\phi}(X) + \text{const}$.

$\mathcal{N} > 4$. HSpin equations with $\mathcal{N} = 8$ –extended supersymmetry

- In the generic case $\{\bar{D}_\alpha^q \Phi(X, \Theta, \bar{\Theta}) = 0, \mathcal{D}_{q[\beta} \mathcal{D}_{\gamma]p} \Phi(X, \Theta, \bar{\Theta}) = 0\} \Rightarrow$

$$\Phi(X, \Theta, \bar{\Theta}) = \phi(X_L) + i\Theta^{\alpha q} \psi_{\alpha q} + \sum_{k=2}^{\mathcal{N}/2} \frac{1}{k!} \Theta^{\alpha_k q_k} \dots \Theta^{\alpha_1 q_1} \mathcal{F}_{\alpha_1 \dots \alpha_k q_1 \dots q_k},$$

$$\mathcal{F}_{\alpha_1 \dots \alpha_k q_1 \dots q_k}(X_L) = \mathcal{F}_{(\alpha_1 \dots \alpha_k) [q_1 \dots q_k]}(X_L), \quad X_L^{\alpha\beta} = X^{\alpha\beta} + 2i\Theta^{q(\alpha} \bar{\Theta}_q^{\beta)},$$

the higher components satisfy $\partial_{\alpha[\gamma} \mathcal{F}_{\delta]\beta_2 \dots \beta_k q_1 \dots q_k}(X_L) = 0$ which is solved in terms of derivatives of new scalar and spinor fields defined up to Peccei-Quinn-like symmetries.

$\mathcal{N} > 4$. HSpin equations with $\mathcal{N} = 8$ –extended supersymmetry

- $\bar{D}_\alpha^q \Phi(X, \Theta, \bar{\Theta}) = 0$, $\mathcal{D}_{q[\beta} \mathcal{D}_{\gamma]p} \Phi(X, \Theta, \bar{\Theta}) = 0$ for $\mathcal{N} = 8$ is solved by

$$\Phi(X, \Theta, \bar{\Theta}) = \phi(X_L) + i\Theta^{\alpha q} \psi_{\alpha q} + \sum_{k=2}^4 \frac{1}{k!} \Theta^{\alpha_k q_k} \dots \Theta^{\alpha_1 q_1} \mathcal{F}_{\alpha_1 \dots \alpha_k q_1 \dots q_k}(X_L)$$
the higher components $\mathcal{F}_{\alpha_1 \dots \alpha_k q_1 \dots q_k}(X_L) = \mathcal{F}_{(\alpha_1 \dots \alpha_k) [q_1 \dots q_k]}$ satisfy

$$\partial_{\alpha[\gamma} \mathcal{F}_{\delta]\beta q_1 q_2}(X) = 0, \quad \partial_{\alpha[\gamma} \psi_{\delta]\beta_2 \beta_3}^q(X) = 0, \quad \partial_{\alpha[\gamma} \mathcal{F}_{\delta]\beta_2 \beta_3 \beta_4}(X) = 0.$$

- which implies $\mathcal{F}_{\alpha\beta q_1 q_2}(X) = \partial_{\alpha\beta} \phi_{q_1 q_2}(X)$,

$$\psi_{\alpha_1 \alpha_2 \alpha_3}^q(X) = \partial_{(\alpha_1 \alpha_2} \tilde{\psi}_{\alpha_3)}^q(X), \quad \mathcal{F}_{\alpha_1 \dots \alpha_4}(X) = \partial_{(\alpha_1 \alpha_2} \partial_{\alpha_3 \alpha_4)} \tilde{\phi}(X).$$

- so that the $\mathcal{N} = 8$ multiplet contains only scalar and s-vector fields

$$\begin{aligned} \partial_{\alpha[\gamma} \partial_{\delta]\beta} \phi(X) &= 0, & \partial_{\alpha[\beta} \psi_{\gamma]}(X) &= 0, \\ \partial_{\alpha[\gamma} \partial_{\delta]\beta} \phi_{qp}(X) &= 0, & \partial_{\alpha[\beta} \tilde{\psi}_{\gamma]}^q(X) &= 0, & \partial_{\alpha[\gamma} \partial_{\delta]\beta} \tilde{\phi}(X) &= 0. \end{aligned}$$

- and defined up to a more complicated P-Q like symmetries:

$$\begin{aligned} \phi_{qp}(X) &\mapsto \phi_{qp}(X) + \mathbf{a}_{qp}, & \tilde{\psi}_\alpha^q(X) &\mapsto \tilde{\psi}_\alpha^q(X) + \beta_\alpha^q, \\ & & \tilde{\phi}(X) &\mapsto \tilde{\phi}(X) + \mathbf{a} + X^{\alpha\beta} \mathbf{a}_{\alpha\beta}, \end{aligned}$$

- 8 Conclusions

$\mathcal{N} > 4$. HSpin equations with $\mathcal{N} = 8$ —extended supersymmetry

- Tensorial superspace provides a beautiful basis to describe free conformal higher spin fields in $D = 4, 6, 10$.
- AdS Flat $\leftrightarrow OSp(1|n)$, flat $\leftrightarrow \Sigma(\frac{n(n+1)}{2}|n)$. ($n = 4, 8, 16$) $D_{[\alpha} D_{\beta]} \Phi = 0$.
- (and also exotic BPS states in M-theory- BPS preons ($n=32$)).
- $OSp(1|2n)$ superconformal symmetry ($OSp(1|8)$ in $D=4$, $OSp(1|32)$ in $D=10$, $OSp(1|64)$ in $D=11$).
- The attempts to describe the HSpin interactions have not succeed (yet?)
- SUGRA in tensorial superspace, formulated with preservation of manifest $GL(n)$ symmetry ($SL(n)$ holonomy) was shown to be superconformally equivalent to either $\Sigma(\frac{n(n+1)}{2}|n)$ or $OSp(1|n)$.
- A possible way is to search for a deformation which breaks (deforms) the $GL(n)$ and $OSp(1|2n)$ symmetry.
- Probably the suggestion will come from studies [Vasiliev, Gelfond, 10, 13] of the currents in $\Sigma(\frac{n(n+1)}{2}|n)$ through the hypothetical
- tensorial AdS/CFT = $\Sigma(\frac{n(n+1)}{2}|n) \leftrightarrow OSp(1|2n)$ correspondence.
- \Leftarrow Flat = $\Sigma(\frac{n(n+1)}{2}|n)$. Its superconf. group = $OSp(1|2n) = AdS^{(n(2n+1)|2n)}$.
