Foreword

This talk is based on

- P. Di Vecchia, "The Birth of String Theory", arXiv:0704.0101.
- PdV and A. Schwimmer, "The Beginning of String Theory: a Historical Sketch".
- Contributions to the Gabriele Veneziano celebrative volume "String theory and fundamental interactions", Ed.s M. Gasperini and J. Maharana, Springer.

Plan of the talk

- 1 N-point amplitude
- 2 Factorization
- 3 Problem with ghosts
- 4 QED
- 5 The Virasoro conditions
- 6 Characterization of physical states
- 7 Scattering amplitudes for physical states
- 8 DDF states and no ghosts
- 9 From DRM to String Theory
- 10 Conclusions

N-point amplitude

Following the principle of planar duality and the axioms of S-matrix theory the scattering amplitude B_N(p₁, p₂,...p_N) for the scattering of N particles was constructed:

$$B_{N} = \int_{-\infty}^{\infty} \frac{\prod_{1}^{N} dz_{i} \theta(z_{i} - z_{i+1})}{dV_{abc}} \prod_{i=1}^{N} \left[(z_{i} - z_{i+1})^{\alpha_{0} - 1} \right] \prod_{j > i} (z_{i} - z_{j})^{2\alpha' p_{i} \cdot p_{j}}$$

- There is a Koba-Nielsen variable z_i for each external particle.
- ► Invariance under the projective group : $z_i \rightarrow \frac{Az_i+B}{Cz_i+D}$. Three of the variables z_i can be fixed: $z_1 = \infty, z_2 = 1, z_N = 0$.
- Only simple poles lying on linearly rising Regge Trajectories:

$$\alpha(\boldsymbol{s}) = \alpha_{\mathbf{0}} + \alpha' \boldsymbol{s}$$

What is the meaning of this amplitude? What is the spectrum of particles?

Paolo Di Vecchia (NBI+NO)

Factorization

Since a particle corresponds to a pole in the scattering amplitude with factorized residue, the "obvious" thing to do was to study the factorization properties of the amplitude at each pole. [Fubini and Veneziano + Bardaçki and Mandelstam, 1969]

Introduce an infinite set of harmonic oscillators
 [Fubini, Gordon and Veneziano; Nambu, Susskind, 1969]

$$[\boldsymbol{a}_{n\mu}, \boldsymbol{a}_{m
u}^{\dagger}] = \eta_{\mu
u} \delta_{nm}$$
 ; $[\hat{\boldsymbol{q}}_{\mu}, \hat{\boldsymbol{p}}_{
u}] = i\eta_{\mu
u}$,

the Fubini-Veneziano operator [Fubini and Veneziano, 1969 and 1970]:

$$Q_{\mu}(z)=Q_{\mu}^{(+)}(z)+Q_{\mu}^{(0)}(z)+Q_{\mu}^{(-)}(z)$$

where

$$Q^{(+)} = i\sqrt{2\alpha'}\sum_{n=1}^{\infty} \frac{a_n}{\sqrt{n}} z^{-n}$$
; $Q^{(-)} = -i\sqrt{2\alpha'}\sum_{n=1}^{\infty} \frac{a_n^{\dagger}}{\sqrt{n}} z^n$

$$Q^{(0)} = \hat{q} - 2i\alpha'\hat{p}\log z$$

and the vertex operator;

$$V(z; p) =: e^{ip \cdot Q(z)} := e^{ip \cdot Q^{(-)}(z)} e^{ip\hat{q}} e^{+2\alpha'\hat{p} \cdot p\log z} e^{ip \cdot Q^{(+)}(z)}$$

In terms of them we can rewrite the N-point amplitude using this operator formalism:

$$egin{aligned} \mathcal{A}_N &\equiv (2\pi)^d \delta^{(d)} (\sum_{i=1}^N p_i) \mathcal{B}_N = \int_{-\infty}^\infty rac{\prod_1^N dz_i heta(z_i-z_{i+1})}{dV_{abc}} imes \end{aligned}$$

$$\times \prod_{i=1}^{N} \left[(z_i - z_{i+1})^{\alpha_0 - 1} \right] \langle 0, 0| \prod_{i=1}^{N} V(z_i, p_i) | 0, 0 \rangle$$

Paolo Di Vecchia (NBI+NO)

(I) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1))

• or introducing the propagator $(L_0 = \alpha' \hat{p}^2 + \sum_{n=1}^{\infty} na_n^{\dagger} \cdot a_n)$:

$$D = \int_0^1 dx x^{L_0 - 1 - \alpha_0} (1 - x)^{\alpha_0 - 1} = \frac{1}{L_0 - 1} = \frac{1}{\alpha' \hat{p}^2 + R - 1} \quad if \quad \alpha_0 = 1$$

we get

$$A_N \equiv \langle 0, p_1 | V(1, p_2) D \dots V(1, p_M) D V(1, p_{M+1} \dots D V(1, p_{N-1}) | 0, p_N \rangle$$

that can be rewritten as follows:

$$A_N(p_1,p_2\dots p_N) = \langle p_{(1,M)} | D | p_{(M+1,N)} \rangle$$

where

$$\langle p_{(1,M)}| = \langle 0, p_1 | V(1, p_2) DV(1, p_3) \dots V(1, p_M)$$

and

$$| p_{(M+1,N)}
angle = V(1, p_{M+1}) D \dots V(1, p_{N-1}) | p_N, 0
angle$$

<ロ> <四> <四> <四> <四> <四</p>

At the pole the amplitude can be factorized by introducing two complete set of states:

$$\mathcal{A}_{\mathcal{N}} = \sum_{\lambda,\mu} \langle \mathcal{p}_{(1,M)} | \lambda, \mathcal{P} \rangle \langle \lambda, \mathcal{P} | rac{1}{\mathcal{R} - lpha(s)} | \mu, \mathcal{P}
angle \langle \mu, \mathcal{P} | \mathcal{p}_{(M+1,N)}
angle$$

• The propagator develops a pole when $(R = \sum_{n=1}^{\infty} na_n^{\dagger} \cdot a_n)$

$$\alpha(s) \equiv 1 - \alpha' P^2 \equiv 1 - \alpha' (p_1 + \dots + p_M)^2 = \sum_{n=1}^{\infty} n a_n^{\dagger} \cdot a_n = m$$

is a non-negative integer ($m \ge 0$).

The residue at the pole α(s) = m factorizes in a finite sum of terms corresponding to the states |μ, P⟩ satisfying the condition:

$$m{R}|\mu,m{P}
angle\equiv\sum_{n=1}^{\infty}na_{n}^{\dagger}\cdot a_{n}|\mu,m{P}
angle=m|\mu,m{P}
angle$$

- The lowest state, corresponding to *m* = 0, is the vacuum of oscillators: |0, *P*⟩ with 1 − α'*P*² = 0.
 This is a tachyon because α₀ = 1.
- The next state with m = 1 is the state: a[†]_{1µ}|0, P⟩ corresponding to a massless vector.
- At the level m = 2 we have the following states $(1 \alpha' P^2 = 2)$:

$$a^{\dagger}_{1\mu}a^{\dagger}_{1
u}|0,P
angle$$
 ; $a^{\dagger}_{2\mu}|0,P
angle$

• At the level m = 3 we have the following states $(1 - \alpha' P^2 = 3)$:

$$a^{\dagger}_{1\mu}a^{\dagger}_{1
u}a^{\dagger}_{1
ho}|0,P
angle$$
 ; $a^{\dagger}_{2\mu}a^{\dagger}_{1
u}|0,P
angle$; $a^{\dagger}_{3\mu}|0,P
angle$

and so on

4 3 5 4 3 5 5

Problems with ghosts

- ► The *N*-point amplitude is Lorentz invariant.
- This forces to factorize the amplitude by introducing a space that is not positive definite:

$$[a_{n\mu}, a^{\dagger}_{m\nu}] = \eta_{\mu\nu} \delta_{nm} ; \eta_{\mu\nu} = (-1, 1, \dots, 1)$$

- Therefore the states with an odd number of time components have a negative norm.
- This is in contradiction with the fact that in a quantum theory the Hilbert space must be positive definite due to the probabilistic interpretation of the norm of a state.
- General problem: how to put together

Quantum theory \Leftrightarrow Special Relativity

QED

 Consider a scattering amplitude in QED near a photon pole. We can write it as follows:

$$A^{\mu}(p_1, \dots p_M, P) \; rac{\eta_{\mu
u}}{P^2} \; B^{
u}(P, p_{M+1} \dots p_N) \; ; \; \; \eta_{\mu
u} = (-1, 1, 1, 1)$$

Naively it seems that the residue consists of four terms and one of them is a ghost corresponding to a negative norm state.

But gauge invariance implies:

$$P_\mu A^\mu = P_\mu B^\mu = 0$$

► In the frame where $P_{\mu} = E(1, 0, 0, 1)$ gauge invariance implies:

$$A_3 - A_0 = B_3 - B_0 = 0$$

They imply that the residue at the photon pole has only two terms:

$$\sum_{i,j=1}^{2} A^{i}(p_{1}, \dots p_{M}, P) \frac{\delta_{ij}}{P^{2}} B^{j}(P, p_{M+1} \dots p_{N}) ; i, j = 1, 2$$

corresponding to the two helicities ± 1 of the photon.

- In this way QED solves the potential conflict between special relativity and quantum theory.
- We can write everything in a covariant way in a space containing negative norm states,
- but then we know that gauge invariance eliminates the unwanted states,
- and the spectrum of physical states is positive definite.
- The physical states are characterized by the "Fermi condition"

$$\partial^{\mu} {\it A}^{(+)}_{\mu} | {\it Phys.}
angle = 0$$

Do we have similar relations in the DRM?

The Virasoro conditions

One such condition was immediately found:

$$|W_1|
ho_{(1,M)}
angle = 0$$
 ; $W_1 = L_1 - L_0$

 L_0 and L_1 can be written in terms of harmonic oscillators.

- It was used to show that there was no negative norm state at the first excited level [Fubini and Veneziano, 1970].
- But it was not enough to eliminate all the non-positive norm states.
- ► Then Virasoro realized that, if $\alpha_0 = 1$, one can find an infinite number of such conditions:

$$W_n | p_{1...M} \rangle = 0$$
; $n = 1...\infty$; $W_n = L_n - L_0 - (n-1)$

[Virasoro, 1969]

and hope that they can cancel all the non-positive norm states.

Characterization of physical states

- Virasoro found the analogous of the condition imposed by gauge invariance.
- But what is the condition that is the analogous of the Fermi condition in QED?
- Those conditions were found proceeding as in QED

 $L_n|Phys., P\rangle = (L_0 - 1)|Phys., P\rangle = 0$; $1 - \alpha'P^2 = m$

[Del Giudice and PDV, 1970]

- At the level m = 1 the analysis reduces to the one in QED.
- At the level m = 2 the physical states are a spin 2:

$$|Phys>_{1} = [a_{1,j}^{\dagger}a_{1,j}^{\dagger} - \frac{1}{(d-1)}\delta_{ij}\sum_{k=1}^{d-1}a_{1,k}^{\dagger}a_{1,k}^{\dagger}]|0,P\rangle$$

with positive norm (i, j are space indices),

$$|\textit{Phys}
angle_2 = \left[\sum_{i=1}^{d-1} a_{1,i}^{\dagger}a_{1,i}^{\dagger} + rac{d-1}{5}(a_{1,0}^{\dagger 2} - 2a_{2,0}^{\dagger})
ight]|0,\textit{P}
angle$$

with norm equal to

$$2(d-1)(26-d)$$
 (1)

that is positive if d > 26.

- The state decouples from the physical spectrum if d =26.
- But the original analysis was done taking for grant that d = 4.... as was...obvious...at that time....
- The absence of ghosts was also shown at the level m = 3, but it was difficult to proceed further.
- The remaining question was: Is the DRM free of ghosts?
- But we had to wait few years to get an answer.

3

Scattering amplitudes for physical states

In the meantime it became clear that the "Virasoro operators" L_n satisfy the algebra of the conformal group in two dimensions:

$$[L_n, L_m] = (n-m)L_{n+m} + \frac{d}{24}n(n^2-1)\delta_{n+m;0}$$

[Fubini and Veneziano, 1970]

including the central charge [Weis, 1970].

The vertex operators corresponding to the physical states are conformal (primary) fields with conformal dimension Δ = 1:

$$[L_n, V_\alpha(z, p)] = \frac{d}{dz} \left(z^{n+1} V_\alpha(z, p) \right)$$

They are related to the corresponding physical states by the relations:

$$\lim_{z\to 0} V_{\alpha}(z; p) |0, 0\rangle \equiv |\alpha; p\rangle \; ; \; \langle 0; 0| \lim_{z\to \infty} z^2 V_{\alpha}(z; p) = \langle \alpha, p|$$

[Campagna, Fubini, Napolitano and Sciuto, 1970]

They satisfy the hermiticity relation:

$$V^{\dagger}_{lpha}(z, \mathcal{P}) = V_{lpha}(rac{1}{z}, -\mathcal{P})(-1)^{lpha(-\mathcal{P}^2)}$$

In terms of these vertices one can write the most general amplitude involving physical states:

$$(2\pi)^4 \delta(\sum_{i=1}^N p_i) B_N^{ex} = \int_{-\infty}^\infty \frac{\prod_1^N dz_i \theta(z_i - z_{i+1})}{dV_{abc}} \langle 0, 0| \prod_{i=1}^N V_{\alpha_i}(z_i, p_i) | 0, 0 \rangle$$

- Complete democracy among physical states.
- A special excited vertex is the one associated to the massless gauge field. It is given by:

$$V_{\epsilon}(z,k) \equiv \epsilon \cdot rac{dQ(z)}{dz} e^{ik \cdot Q(z)}$$
; $k \cdot \epsilon = k^2 = 0$

DDF states and no ghosts

Using the vertex operator corresponding to the massless gauge field one can define the DDF operator:

$$A_{i,n} = \frac{i}{\sqrt{2\alpha'}} \oint_0 dz \epsilon_i^{\mu} P_{\mu}(z) e^{ik \cdot Q(z)} ; 2\alpha' p \cdot k = n$$

 p_{μ} is the four-momentum of the states on which it acts • and

$$P(z) \equiv \frac{dQ(z)}{dz} = -i\sqrt{2\alpha'}\sum_{n=-\infty}^{\infty} \alpha_n z^{-n-1}$$

They are physical operators

$$[L_m,A_{n;i}]=0$$

and they satisfy the algebra of the harmonic oscillators:

$$[A_{n,i}, A_{m,j}] = n\delta_{ij}\delta_{n+m;0}$$
; $i, j = 1...d-2$

[Del Giudice, DV and Fubini, 1971]

Paolo Di Vecchia (NBI+NO)

(I) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1))

In terms of this infinite set of transverse oscillators we can construct an orthonormal set of states:

$$|i_1, N_1; i_2, N_2; \dots i_m, N_m\rangle = \prod_h \frac{1}{\sqrt{\lambda_h!}} \prod_{k=1}^m \frac{A_{i_k, -N_k}}{\sqrt{N_k}} |0, p\rangle$$

- Is it complete? Does it span the entire space of physical states?
- This was checked for d = 4 and in this case the DDF states are not complete.
- There are additional states that were called Brower states.
- They are complete if d = 26.
- They span a positive definite Hilbert space: no ghosts if d = 26.
- ► The proof of no ghosts was then extended to any *d* ≤ 26. [Brower and Goddard and Thorn, 1972]

3

- This number (d = 26) had already appeared a couple of years before [Lovelace, 1970].
- It was required in order to avoid a violation of unitarity in the twisted loop.
- But almost nobody took it seriously.
- It was very difficult (also psicologically at that time) to think of a theory for strong interactions in *d* ≠ 4 !!!
- Now after the proof of the no ghost theorem everybody started to accept it.
- After about four years of hard work the basic properties of the DRM were understood.
- Also loop diagrams to implement unitarity were constructed using the sewing procedure. Functions well defined on Riemann surfaces were generated by the sewing procedure. [Alessandrini and Amati, 1971]
- But it was still unclear in 1972 what the underlying structure was.

ъ

From DRM to String Theory

- The existence of an infinite number of harmonic oscillators brought already in 1969 some people to suggest that the underlying structure was that of a relativistic string.
 [Nambu, Nielsen, Susskind, 1969]
- A Lagrangian was written that was a generalization to two dimensions of the one for a pointlike particle in the proper time gauge:

$$L \sim \frac{1}{2} \frac{dX}{d\tau} \cdot \frac{dX}{d\tau} \Longrightarrow L \sim \frac{1}{2} \left[\frac{dX}{d\tau} \cdot \frac{dX}{d\tau} - \frac{dX}{d\sigma} \cdot \frac{dX}{d\sigma} \right]$$

- Being the Lagrangian conformal invariant the generators of the conformal group were also constructed.
- But in this formulation this symmetry was just a "global" symmetry that did not imply the vanishing of the classical generator:

$$L_n = 0$$

イロト 不得 トイヨト イヨト

A non-linear string Lagrangian was also proposed that was invariant under arbitrary reparametrizations of the world-sheet coordinates σ and τ:

$$S = -cT \int_{\tau_i}^{\tau_f} d\tau \int_0^{\pi} d\sigma \sqrt{(\dot{X} \cdot X')^2 - \dot{X}^2 X'^2}$$

[Nambu and Goto, 1970]

- But it took three years to show that the spectrum and the critical dimension (*d* = 26) followed from it.
 [Goddard, Goldstone, Rebbi and Thorn, 1973]
- Immediately after also the scattering amplitudes of the DRM were derived from string theory [Ademollo et al. + Mandelstam, 1974].
- In particular, the Fubini-Veneziano operator is the open string coordinate:

$$Q(z)
ightarrow X(e^{i au}, \sigma=0)$$
 ; $z=e^{i au}$

3

< 日 > < 同 > < 回 > < 回 > < 回 > <

Conclusions

- It took 4 years (1969-1973) to understand the perturbative properties of the DRM (physical spectrum and scattering amplitudes at tree, one-loop and multiloop level).
- Only the integration measure in multiloop diagrams was determined later.
- Actually at one-loop level it was determined in 1973 using the Brink-Olive projection operator.
- In this period (1969-1973) the fact that the underlying theory may be a string theory played a very minor role.
- But some problems were left unsolved, namely the presence of a tachyon and the 26 dimensions....

イロト 不得 トイヨト イヨト
